INTRODUCTION

The Air Force Office of Scientific Research Technical Report Summaries are published quarterly as of March, June, September, and December of each calendar year. They consist of a brief summary of each AFOSR technical report received in the Technical Information Division and submitted to the Defense Technical Information Center (DTIC) for that quarter. The summaries contain two indexes for easily locating the technical reports that may be of interest to the user. These are followed by abstracts of the reports.

1) SUBJECT INDEX --

- a. Subject Field,
- b. Title of Report,
- c. AD Number (Accession Number),

2) PERSONAL AUTHOR INDEX --

- a. Primary Author,
- b. Title of Report,
- c. AD Number.

AFOSR does not maintain copies of technical reports for distribution. However, you may obtain any of these reports if you are a registered government agency or government contractor with DTIC, by requesting the AD number of that report from the DTIC, Cameron Station, Alexandria, Virginia, 22314.

PURPOSE

The purpose of this report is to inform Air Force Laboratories about the science that the Air Force Office of Scientific Research is supporting.

AFOSR MISSION

The Air Force Office of Scientific Research (AFOSR) is the Single Manager of the Air Force Defense Research Sciences Program (Program Element 61102F) and the primary Air Force agency for the extramural support of fundamental scientific research. The AFOSR is organizationally under the DCS/Science and Technology, Air Force System: Command.

AFOSR awards grants and contracts for research in areas of science relevant to the needs of the Air Force. Research is selected for support from proposals received in response to the Broad Agency Announcement originating from scientists investigating problems involving the search for new knowledge and the expansion of scientific principles. Selection is on the basis of scientific potential for improving Air Force operational capabilities, originality, significance to science, the qualification of the principal investigators, and the reasonableness of the proposed budget.

KEY TO READING THE DATA

The summaries consist of two indexes and the abstracts. From one of the two indexes, locate the AD number of the report that is of interest to you. Use this number to locate the abstract of the report in the abstracts section. The first report submitted to DTIC during the quarter (the one with the lowest AD number) appears on the last page of the abstracts section. The last report submitted to DTIC during the quarter (the one with the highest DTIC number) appears on the first page of the abstracts section. The following terms will give you a brief description of the elements used in each summary of this report.

DTIC Report Bibliography - DTIC's brief description of a technical report.

Search Control Number - A number assigned by DTIC at the time a bibliography is printed.

AD Number - A number assigned to each technical report when received by the DTIC.

Field & Group Numbers - (appearing after the AD number) First number is the subject field and the second number after the slash is the particular group under that subject field.

Corporate Author/Performing Organization - The organization; e.g., college/university, company, etc., at which the research is conducted.

Title - The title of the technical report.

Descriptive Note - Gives the type of report; e.g., final, interim, etc., and the period of the time of the research.

Date - Date of the technical report.

Pages - Total number of pages contained in the technical report.

Personal Author - Person or persons who wrote the report.

Contract/Grant Number - The instrument control number identifying the contracting activity and funding year under which the research is initiated.

Project Number - A number unique to a particular area of science; e.g., 2304 is the project number for mathematics.

Task Number - An alphanumeric number unique to a specific field of the main area of science; e.g., 2304 is the project number for mathematics and A3 is the task number for computational sciences.

Monitor Number - The number assigned to a particular report by the government agency monitoring the research. The number consists of the government monitor acronym, the present calendar year and the technical report assigned consecutively; e.g., AFOSR-TR-83-0001 is the first number used for the first technical report processed for Calendar Year 1983.

Supplementary Note - A variety of statements pertaining to a report. For example, if the report is a journal article, the supplementary note might give you the journal citation, which will include the name of the journal the article it appears in, and the volume number, date, and the page numbers of the journal.

Abstract - A brief summary describing the research of the report.

Descriptors - Key words describing the research.

Identifiers - Commonly used designators, such as names of equipment, names of projects or acronyms, the AFOSR project and task number, and the Air Force Research Program Element number.

Summary Abstract: Surface Vibrational Resonances and the Order-Disorder Transformation of the W(100) Surface.
AD-A189 192

Summary of Equipment Purchased and Description of Its Use: Support of Research in Beamed Energy Propulsion.
AD-A187 952

Supercomputers for Solving PDE (partial Differential Equations) Problems.
AD-A186 583

Superconductivity of Thin Film Intermetallic Compounds.
AD-A187 583

Supersonic Flow Past Circular Cones at High Angles of Yaw, Downstream of Separation.
AD-A186 250

Support for Concurrent Computing Environments.
AD-A188 498

Symbolic Cholesky Factorization on a Local-Memory Multiprocessor.
AD-A187 020

Symposium on Molecular Spectroscopy (42nd) Held in Columbus, Ohio on June 15-19, 1987.
AD-A186 341

A Synopsis of Elliptic PDE (Partial-Differential-Equation) Models for Grid Generation.
AD-A185 346

Syntheses of (Difluoroamino)Difluoroacetonitrile, Syn-Fluoro(Fluoroimino)Acetonitrile, and Syn-3,3,3-Trifluoro-2-(Fluoroimino)Propanenitrile and Their Reactions with Chlorine Fluoride. Syntheses of New Perfluorinated Diazires.
AD-A187 018

Syntheses of New Substituted Pentacyclo(5.4.0.0(2,6).0(3,10).0(5,9))decanes: A Novel Synthesis of Hexacyclo(6.2.1.1(3,6).0(2,7).0(4,10).0(5,9))dodecane (1,3-Bis(homopentaprismane)).
AD-A189 098

Syntheses of Nitro-Substituted 2,3,4,8-Tetrahydropentacyclo(5.3.0.0(2,5).0(3,9).0(4,8))decanes.
AD-A189 099

Synthesis and Characterization of Thin Films.
AD-A187 335

The Synthesis and Molecular Structure of a Disilacyclopentanamine.
AD-A187 662

Synthesis and X-Ray Structure of Cis-1,3-Di-Tert-Butyl-2,4-Bis(Pentafluorophenoxy)-1,3,2,4-Diazadiphosphetidine.
AD-A185 339

Synthesis of Symmetrical Bis(aryl)sulfur Diimides.
AD-A187 656

Tactile Sensing and Inverse Problems.
AD-A187 464

Test of Linearity in General Regression Models.
AD-A186 036

Testing and Interval Estimation in a Change-Point Model Allowing at Most One Change.
AD-A185 525

Testing Exponentiality Versus a Trend Change in Mean Residual Life.
AD-A185 587

Theoretical Investigations of Chaotic Dynamics.
AD-A186 404

Theoretical Studies of Kinetic Mechanisms of Negative Ion Formation in Plasmas.
AD-A185 735

Theory and Practice of Fault Tolerance in Distributed Systems.
AD-A187 559

Theory of Laser-Simulated Surface Processes. 3. Desorption through Vibrational Excitation by an IR laser.
AD-A187 567

Theory of Two-Photon Emission from Atomic Inner Shells.
AD-A187 742

Three-Dimensional Non-Axisymmetric Anisotropic Stress Concentrations.
AD-A185 392

Three-Dimensional Structure of Boundary Layers in Transition to Turbulence.
AD-A185 466

A Three-Parameter Generalisation of the Beta-Binomial Distribution with Applications.
AD-A185 733

Time-Consistent Pressure Relaxation Procedure for Compressible Reduced Navier-Stokes Equations.
AD-A186 507

Time Delays and Boundary Feedback Stabilization in One-Dimensional Viscoelasticity. Appendices A thru H.

UNCLASSIFIED REPORT

ABSTRACT: (U) In developing an approach to determining diagnostics for intelligent control of MPD thrusters, two concurrent studies have been carried out: a stability analysis, and a plasma modeling. An advanced technique for derivation of stability requirements of distributed parameter systems based on mathematical theorems of semigroups and groups, equivalent norms, Lyapunov functionals, etc. has been developed. Application of this technique to the MPD thrusters has resulted in control inputs for stabilizability of the system when perturbed from a general equilibrium state of the plasma. A model has been developed for the state of plasma near the cathode of a MPD thruster engine. The region has been divided into collisionless and collisional parts and full account is taken of the non-equilibrium state of the plasma over the entire region. A scheme for solving the set of describing equations based on an iterative procedure has been developed. For low and high current inputs, it is expected that the extent of the different regions will change indicating the trends towards the arising of onset instability. Keywords: Plasma dynamics; MPD modeling; Stability; Controllability; Observability; Nonlinear systems; Distributed parameter systems.

UNCLASSIFIED REPORT

ABSTRACT: (U) Modifications to three major facilities at Caltech, carried out in preparation for an extensive investigation of shock enhanced mixing and combustion in supersonic combustion ramjets, has progressed according to schedule. Work is complete on the GALCIT 17-inch shock tube and on the Unsteady Combustion Facility, and they are operating as planned. Extensive improvement of the optical diagnostics and data acquisition equipment for both of these is nearly complete. Design of the new heated-hydrogen leg for the Hydrogen/Fluorine facility has been simplified considerably from the original concept and is progressing satisfactorily. Extensive computational studies of the interaction between weak shock waves and isolated regions of hydrogen embedded in air has revealed a behavior which suggests that considerable technological advantage may accrue by the use of multiple weak shocks to enhance mixing. Keywords: Supersonic combustion; Vortex burning mixing; Shear layers vorticity generation; Shock enhanced mixing.

UNCLASSIFIED REPORT

ABSTRACT: (U) Substantial advances in the analysis of the large-amplitude unsteady aerodynamics of wings have been achieved. Special focus has been placed on developing techniques for describing the exact non-linear convection, deformation, and roll-up of the vorticity wakes above and behind active wing surfaces. Using a combination of analytic and computer-interactive methods, new insights and more exact aerodynamic performance results have been generated. The effects of dissipative internal 'cores' in the overall 3D wake structures above deltas have been analyzed in the slender wing limit. New paths for further computer-assisted advances, including improved understanding of wing-wake interaction in severe maneuver, vortex core formation and break-up, and aerodynamic history effects have been charted. Papers are included on the following topics: Nonlinear aerodynamics of two-dimensional airfoils in severe maneuver; Interactive aerodynamics of wings in severe maneuver; Slender wing theory including regions of embedded total pressure loss; Keywords: Unsteady wing theory; Wake evolution; Vortex core evolution; Flight maneuvers; Unsteady wing loads; Flight loads.

UNCLASSIFIED REPORT

ABSTRACT: (U) The general objective of this work is to control jet flows by properly organizing the dominant large-scale vortex structures. The work has focused on understanding the influence of excitation frequency and amplitude on the large-scale structures of these flows at various Reynolds numbers. Specifically, the effects of dual-mode forcing on the structure, momentum, and mixing characteristics of turbulent jets have been investigated using a combination of laboratory experiments and numerical simulations. The combination of properly-selected axial and orbital excitation has been shown to have dramatic effect on the structure and mixing of round jets. Experiments and numerical simulations show that these phenomena are due to interaction between the large-scale vortices in the jet near field. The position and phasing of these vortices can be altered by relatively weak excitation, causing the jet to divide into two separate jets (bifurcation) or to explode (bloom) in a shower of vortex rings. This report summarizes the key results of studies in water and low-speed air flows.

ABSTRACT: (U) The completed research was directed at fundamental investigations of ultra fast chemical reactions, the generation and decay of reactive chemical intermediates, as well as the role of the solvent and molecular motions on chemical dynamics. The construction of an amplified CPM laser enabled the opportunity to prove chemical events occurring in the femtosecond time domain. The effects of molecular geometry, solvent and solute steric effects, on the chemical dynamics was explored. An important new component of the research was the studies of chemical phenomena on surfaces as well as in bulk media. The asymmetry of forces associated with liquid surfaces was found to impose new restraints and possibilities on the generation of chemical species; thus affecting the chemical species lifetimes, motions and pathways for reaction.

UNCLASSIFIED REPORT

ABSTRACT: (U) This program was aimed at understanding the number and types of sources found in the fields observed with greatest sensitivity by the IRAS satellite. The initial phase of the study emphasized observation and analysis of sources found in the less sensitive all sky survey carried out with Infrared Astronomy Satellite. Significant differences between the bright and faint 12 um sources were found, which constrain their relative spatial distributions and luminosities. A study focussed on one, large population of infrared-bright stars -- those whose atmospheres are rich in carbon -- yielded measurements of their space distribution range of mass loss rates, and lifetimes. An analysis of 60 um sources from the IRAS survey showed that eighty-five percent of those located more than thirty degrees above the plane of the Galaxy are extragalactic objects, provided a measure of the space density of galaxies of different infrared luminosities, and showed that there are significant differences in the environment and infrared properties of the most luminous and least luminous galaxies. Studies of galaxies with particularly strong mid-infrared emission resulted in the discovery of ultraluminous objects. Initial studies of results from the IRAS pointed observations show effects of contamination by low-surface-

ABSTRACT: (U) Silylene, generated from the thermal decomposition of silane between 643 and 689 K, reacts with 1-butene to produce n-butyl- and sec-butylsilylene and cis- and trans-2-butene. The mechanism of the reaction involves butylsilylene and silacyclopropane intermediates. Sec-Butylsilylene isomerizes to 2,3-dimethylsilacyclopentane with an activation energy for = 11.6 + or - 2.6 kcal, while the activation energy for the decomposition of 2,3-dimethylsilacyclopentane (to 2-butenes and silylene) is significantly higher than the activation energy for its back reaction to sec-butylsilylene, (E22-E-21) = 11.5 + or - 0.5 kcal. Further the decomposition of the silacyclopentane is several times faster than its isomerization, indicating a high A factor and consecutive step, biradical mechanism for the decomposition.

white.

ABSTRACT: (U) Simultaneous data obtained with the
Chatanika incoherent scatter radar and the Dynamics
Explorer 2(DE2) and NOAA 6 satellites are used to relate
the locations of the precipitating particles, field-
aligned currents, and E and F region ionization
structures in the evening-sector auroral oval. The
auroral - E layer observed by the radar extends about 2
deg equatorward of the electron precipitation region, and
its equatorward edge coincides with the equatorward edges
of the region 2 field-aligned current and intense
convection region (E approx. 50 mV/m). It is shown that
precipitating protons are responsible for part of the E
region ionization within the electron precipitation
region as well as south of it. E region density profiles
calculated from ion spectra measured by the DE2 and NOAA
6 satellites are in fairly good agreement with the
Chatanika data. In the F region, a channel of enhanced
ionization density, elongated along the east-west
direction and having a width of about 100 km, marks the
poleward edge of the main trough. It is collocated with
the equatorward boundary of the electron precipitation

from the central plasma sheet. Although enhanced fluxes of soft electron are observed at this boundary, the energy input to the ionospheric electron gas, calculated from the radar data, shows that this ionization channel is not locally produced by this soft precipitation, but that it is rather a convected feature. In fact, both the trough and the ionization channel are located in a region where the plasma flows sunward at high speed, but the flux tubes associated with these two features have different convective time histories.

ABSTRACT: (U) It is proposed to measure the line intensities and profiles of the 83 micrometer 3P sub 1 - 3P sub 2 transition and 147 micrometer 3P sub 0 - 3P sub 1 transition of the ground electronic state of atomic oxygen from a space-borne platform in a limb-viewing mode. The temperature and atomic oxygen density can be obtained by inversion from the total radiances in the two channels. The line profiles provide a confirmation of temperature and, in addition, yield the component of the wind speed along the line-of-sight. In the optically thick regime (below tangent height < 170 KM for 63um line), the radiation escapes primarily from the pressure-broadened portions of the line. This permits a determination of the pressure if we know the pressure-broadening coefficient and its dependence upon temperature.

ABSTRACT: (U) Summary: The ultraviolet photolysis of linear trisilanes in 2-MeTHF at 77 K has led to the first spectroscopic detection of silylene ether complexes. The complexes are also formed during the annealing of mixed 3-MP/2-MeTHF glasses. Chemical evidence for complexed silylenes based on competitive trapping studies as well as evidence that the silylene-ether complexes have a significant life time in solution at low temperatures is presented. The isolation of silylenes in argon or hydrocarbon matrices has in recent years contributed greatly to the knowledge of these reactive species. Here we report the results of recent investigations of diorganosilylenes in pure 2-methyltetrahydrofuran (2-MeTHF) glasses and in 3-methylpentane (3-MP) matrices containing ether dopants, leading to the first spectroscopic observation of silylene ether complexes.

ABSTRACT: (U) Few exact solutions for collisional presheaths exist because of the difficulty of simultaneously satisfying both the collisional Boltzmann equation and the Poisson equation. The exact solutions that do exist are for very specialized collision terms such as constant cross-section charge exchange with cold neutrals. The present paper presents an asymptotic method which is applicable to a variety of collision terms and is applied in particular to constant collision frequency charge exchange with noncold neutrals. Constant collision frequency and constant cross-section collision with cold neutral results are also presented. The first order terms for the presheath potential rise and ion distribution functions are calculated and it is shown that second- and higher-order terms can be calculated using a multipotential expansion for presheath potential rise. The first-order cold neutral constant cross-section results correspond well to the exact solution. The calculated presheath potential rises are of the order expected from the Bohm criterion, and in some of the specialized cold neutral cases, exactly $k e/2$. The presheath potential rise is reduced by a neutral plasma potential gradient which accelerates ions toward the

ABSTRACT: (U) A general purpose computer program has been developed to calculate atomic fluorescence curves of growth (COG) for a wide variety of cases and particularly for the experimentally interesting cases where the excitation source spectral bandwidth is not much different from the absorption linewidth in typical flames and plasmas. Calculations over a wide range of the variables which affect the shape of the COG in the high-number-density region show that the point of departure from linearity can be used to predict the absolute number density in the atomizer cell. For resonance atomic fluorescence, the point at which the experimental curve of growth is twofold below the low-density linear asymptote invariably occurs at k_0L (peak absorption coefficient \times absorption pathlength) product of 2 + or - .

ABSTRACT: (U) In recent development of adaptive optics,
the problem of shape control of a deformable mirror is
studied. Assume that the mirror is modelled by a thin
elastostatic plate. At certain interior points of the
plate a number of sensors are located which measure the
deformation at those points. We wish to apply boundary
controls to the plate so that the sensory data are as
close to the prescribed values as possible. In this paper
we present a boundary element method to approximate
optimal boundary controls for quadratic cost problem. The
method has been tested to have high accuracy and
efficiency. Preliminary numerical results are also
presented.

ABSTRACT: (U) With the recent advances in Si molecular
beam epitaxy (MBE), a heterojunction-based device
technology for Si may soon be at hand. Strained-layer
Si(1-x)Ge(x) epitaxial alloy films and coherently
strained Si(1-x)Ge(x)/Si multilayer structures have been
grown very successfully by MBE. Si(1-x)Ge(x) systems are
of considerable interest because they promise to extend
the capabilities of heterojunction-based devices to the
already well established realm of Si technology. The
major impact of heterojunction technology applied to Si
electronic devices is expected to twofold: in the
performance improvement of certain conventional Si
devices such as the n-p-n bipolar transistor, and in the
development within Si technology of novel device
structures such as the High Electron-Mobility Transistor
(HEMT).

ABSTRACT: (U) The objective of this study is to determine the effect of microstructural properties on the fatigue crack propagation (FCP) response of nickel base superalloys. This report describes the results of four experimental alloys containing various amounts of aluminum, titanium, and molybdenum. Chemistry, precipitate size, and grain size were varied to produce systematically controlled microstructures. The four alloys were characterized for chemical composition, microstructure, tensile properties, low cycle fatigue (LCF), and FCP resistance. The FCP tests were performed under constant load (increasing K) conditions in air at a stress ratio (R) of 0.1 and 0.8. Closure loads were measured with a clip gage, back-face strain gage, and a laser extensometer. Keywords: Fatigue crack propagation, Nickel base superalloys, Microstructure, Closure, Mismatch, Anti phase boundary.

ABSTRACT: (U) The principal investigator considered a number of mathematical problems that may help explain material failures in polymers and ductile metals. In particular, useful results were obtained concerning the initiation and dynamic growth of holes, the static instability and surface cracking of a single hole and the linearized stability of a free surface in an elastic material.

ABSTRACT: (U) Results have been obtained by Fourier Transform Infrared Emission Spectrometry (FTIES) to determine the internal energy distribution in molecules whose states are consequent to three kinds of inelastic and/or reactive collision processes. (1) Free jet Expansion. Gas that is vibrationally excited in the source by heating, corona discharge or chemical reaction is interrogated by FTIES after free jet expansion into vacuum. The observed marked departures from equilibrium give insight on RR, RT, RV and VV exchanges where R, T and V refer to rotational, vibrational and translational energy. (2) Inelastic Scattering from Surfaces. When free jets of CO₂, CO₂, N₂O, and OCS are incident on a hot Pt surface the reflected molecule have enough vibrational excitation to be analyzed by FTIES. Vibrational and Rotational accommodation coefficients have been determined for these species over a range of surface temperatures. (3) Reactive Scattering from Surfaces. FTIES analysis has been carried out on nascent carbon dioxide molecules formed by the catalytic oxidation of carbon monoxide molecules incident on a Pt surface bathed in oxygen. Results indicated vibrational and rotational temperatures much higher than surface temperatures.

ABSTRACT: (U) Many problems in structural dynamics involve stabilizing the elastic energy of partial differential equations such as the Euler-Bernoulli beam equation by boundary conditions. Exponential stability is a very desirable property such elastic systems. The energy multiplier method has been successfully applied by several people to establish exponential stability for various PDEs and boundary conditions. However, it has also been found that for certain boundary conditions the energy multiplier method is not effective in proving the exponential stability property. A recent theorem of F. L. Huang introduces a frequency domain method to study such exponential decay problems. In this paper, we derive estimates of the resolvent operator on the imaginary axis and apply Huang's theorem to establish an exponential decay result for an Euler-Bernoulli beam with rate control of the bending moment only. We also derive asymptotic limits of eigenfrequencies, which was also done earlier by P. Rideau. Finally, we indicate the realizability of these boundary feedback stabilization schemes by illustrating some mechanical designs of passive damping devices.

ABSTRACT: (U) The mechanism underlying genetic variation
in the acute and chronic responses of mice to
diisopropylphospho-fluoridate (DFP) are unknown. We
investigated whether variation in metabolism of
organophosphates by A-esterase, as exemplified by the
enzyme paraoxonase, was correlated to the degree of
sensitivity to DFP in four inbred mouse strains. LD50s
and plasma paraoxonase were measured in each strain. We
observed genetic variation in both of these measures, but
there was no significant correlation between the two
measures. We conclude that plasma paraoxonase activity
does not underlie genetic variation in sensitivity to the
lethal effects of DFP in mice since it does not determine
the degree of sensitivity or resistance to DFP.

UNCLASSIFIED REPORT

ABSTRACT: (U) Important elementary gas phase reactions have been studied by the discharge flow technique, utilizing laser induced fluorescence to detect radical species and mass spectrometry to monitor stable reaction products. Both rate constants and reaction products have been determined. The H-abstraction reactions of F atoms and of OH radicals with CH₃OH favor different reaction channels: the former yields predominantly methoxy radicals (CH₃O), whereas the latter strongly favors hydroxymethyl (CH₂OH). The reaction of OH with CH₃OH shows a large kinetic isotope effect for this channel. The kinetics of CH₃O with NO resemble those of CH₃O with NO₂ studied previously in this lab, namely a weak positive pressure dependence and a strong inverse temperature dependence and a strong inverse temperature dependence of the second order rate coefficient. Analysis of the rate data together with direct detection of reaction products have established that atom transfer to yield HNO + CH₂O is the major channel at low pressures. A brief study of the reaction of NH₂ with NO has shown that OH production is a minor channel, with a branching fraction of ≤ 0.04 . Keywords: Chemical kinetics; Elementary reactions; Methoxy radicals; Laser induced fluorescence.

ABSTRACT: (U) Temperature-programmed reflection absorption infrared spectroscopy (TPRAIS), in concert with reflection absorption infrared spectroscopy (RAIS), was used to follow the sequence of stable surface intermediates for the decomposition of acetic acid monomer and dimer on Ni(100). After acetic acid monomer adsorbs molecularly at 170 K, the acid hydrogen is irreversibly lost at 240 K and a bridge-bonded acetate is formed. The bridge-bonded acetate then under-goes a reversible transformation to a monodentate acetate above 320 K which eventually decomposes to CO₂, C(ad), and H₂ at 435 K. Acetic acid dimer adsorbs molecularly at 170 K with the hydrogen-bonded ring approximately parallel to the surface. The dimer decomposes by dehydration at 255 K to adsorbed CO, a bridge bonded acetate, and an adsorbed methyl group. The acetate decomposes to CO₂, C(ad), and H₂ at 440 K. The key step in the acetate decompositions is the C-C bond scission. The dynamic infrared study shows the importance of performing the spectroscopy at reaction conditions to identify the stable molecular configurations involved during the reaction. Keywords: Reflection spectroscopy; Infrared; Acetic acid; Nickel.

ABSTRACT: (U) This paper surveys recent advances in stochastic comparisons of order statistics along with reliability applications. Section 2 presents inequalities for linear combinations of order statistics from restricted families. Comparisons of linear combinations of order statistics from distributions F and G are obtained for/G F convex and for/G F starshaped. These results yield conservative upper and lower tolerance limits. For G exponential and F IFR or IFRA, stochastic comparisons are presented for the total time on test, used in life testing. Section 3 presents stochastic comparisons of order statistics from underlying heterogeneous distributions. Given two sets of independent components (possibly unlike), majorization conditions are given which insure that any k-out-of-n system constructed from components in the first set will have reliability at least as great as that of a corresponding system constructed from components in the second set. Since the ordered failure times of the components represent order statistics from heterogeneous distributions, the order statistics from one set of underlying distributions (F_1, \dots, F_n) can be compared stochastically with those from another set (F_1, \dots, F_n) .

IDENTIFIERS: (U) Bootstrap problems, Jackknife problems, Bias reduction.

ABSTRACT: (U) During the second year of this project progress was made in the following areas concerned with the effect of alloying elements on the corrosion resistance of RSP Mg alloys: (1) The development of the surface reflection x ray spectroscopic technique (reflexAFS) to carry out structural studies on the films on Mg alloys that control corrosion was completed and applied in measurements at the oxygen K-edge of surface films on high purity Mg and AZ61 Mg alloys. The existence of magnesium hydroxide on these surfaces was found. (2) Electrochemical studies of the effect of Al, An, Ce, Nd, Y, Mn, Li, and Ca in melt-spun Mg alloy ribbons on corrosion behavior were carried out. The corrosion rate decreased with increased percentage of Al and small additions of Zn. It was found that rapid solidification improves the resistance of the alloy studied (AZ61) to localized C1- attack. (3) Surface analytical studies found that only Li and Ca in the RSP Mg alloys have a tendency to be enriched in the films on these alloys. Hydroxides and carbonates were also found in the surface films along with oxides. Keywords: Magnesium alloys, Rapidly solidified alloys, Corrosion, EXAFS, Electrochemistry, Localized corrosion, Passivity.

UNCLASSIFIED REPORT

ABSTRACT: (U) This report reviews progress made during the first year of a two year Phase II SBIR program to develop the Saccade Length Index of Mental Workload or SLIT. The ultimate goal of this effort is to develop a fully portable system to measure workload using the SLIT metric. Phase I work showed that workload and saccade length were related when workload was manipulated using an auditory tone counting task. Research conducted thus far in Phase II has replicated the Phase I results and has also shown 1) that the saccade length index is not affected by extended practice on a difficult tone counting task, and 2) that practice on a difficult tone measure when subjects perform less difficult levels of the same task. Preliminary results suggest that saccade length reflects workload on visual counting tasks in addition to auditory counting tasks, thus extending the possible application of SLIT to visual tasks which do not require precise visual fixation or tracking. Hardware has been purchased for the SLIT system and progress has been made on software development so that SLIT system may be automated for data collection and analyses. Keywords: Biocybernetics, Human performance.

UNCLASSIFIED REPORT

ABSTRACT: (U) This project is concerned with several questions concerning the existence, uniqueness continuous data dependence and numerical computation of solutions of various ill posed problems in partial differential equations. Several problems involving reaction diffusion equations with and without convection terms present were studied. In the latter case the ability of finite element approximate solutions to reproduce the continuous time dynamics was investigated. In the former case a convective diffusion equation with a similar source in the boundary condition was analyzed. A fairly complete picture of the dynamics was obtained. With the source term in the equation, computations revealed a rich structure which has been partially analyzed theoretically. Several problems for reaction diffusion equations in unbounded regimes were also investigated. It was shown that under certain conditions in the rate law all nonzero solutions blow up in finite time, while for other conditions in the rate law, solutions damp out.

DESCRIPTORS: (U) *NUMERICAL METHODS AND PROCEDURES, *PARTIAL DIFFERENTIAL EQUATIONS, BOUNDARIES, COMPUTATIONS, CONVECTION, DIFFUSION, DYNAMICS, FINITE ELEMENT ANALYSIS, NUMERICAL ANALYSIS, RATES, SOLUTIONS (GENERAL), POTENTIAL THEORY, EIGENVALUES, CAUCHY PROBLEM.

ABSTRACT: (U) THE ANNEALING ALGORITHM IS A POPULAR Monte-
Carlo algorithm for combinatorial optimization. The
annealing algorithm consists of simulating a
nonstationary finite state Markov chain whose state space
is the domain of the cost function, called energy, to be
minimized. The degree of randomization in the annealing
algorithm is controlled by a parameter, called
temperature, which is slowly decreased to zero. The
convergence in probability and the rate of convergence of
the annealing chain for the special case of an energy
function with two local minima is analyzed. The sample
path properties of annealing chains (with arbitrary
energy functions) are examined. A modification of the
annealing algorithm which makes noisy measurements of the
energy function is given. The annealing algorithm is
extended for optimization on general spaces.

ABSTRACT: (U) The paper presents a theory of stochastic evolution equations for nuclear space valued processes and provides a unified treatment of several examples from the field of applications. (C sub 0,1) reversed evolution systems on countably Hilbertian nuclear spaces are also investigated. Keywords: Nuclear space, Stochastic evolution; Time dependent evolution; Interacting.

ABSTRACT: (U) Let (B, \cdot) be a complete separable Banach space and let $X=X(B)$ be the vector space of all random variables defined on a probability space (Ω, \mathcal{A}, P) and taking values in B . It is known that metrics on X of convolution type enjoy a variety of interesting properties. In this article it is shown that convolution metrics may also be used to obtain rates of convergence in CLT's involving a stable limit law. The rates are expressed in terms of a variety of uniform metrics on X and include the total variation metric and the uniform metrics between density and characteristic functions. The results represent both an improvement and an extension of existing results. Weak convergence properties of convolution metrics are also explored. Keywords: Ideal probability metrics; Convolution metrics; Rate of convergence; Stable random variables.

ABSTRACT: (U) The first Very Large Array (VLA) observations of the Sun at 92 cm wavelength (328 MHz) are presented. A solar noise storm, which lasted at least 3 hr, was detected at this wavelength; it consisted of a burstlike spikes superposed on a slowly varying background, and both components were 95% + or - 5% right-hand circularly polarized. A long-duration soft X-ray event preceded the radio radiation by 30 minutes, suggesting a disturbance moving outward at a velocity of v=78 km/s. The 92 cm noise storm was resolved with an angular resolution 9 arc sec for time intervals as short as 13 s. Snapshot maps revealed a persistent elongated source at successive peaks, with a scatter in the source position. A systematic position shift of Delta Theta > or = 15 can be produced by the Earth's ionosphere, but these effects can be removed by frequent observations of a nearby calibrator source. Previously reported trends are confirmed for a decrease in source size at higher frequencies. The new VLA results are also consistent with previous observations of noise storm polarization and height. The VLA can potentially resolve both the burst and continuum components of noise storms, while also detecting the effects of anisotropic scattering in the corona. The high angular resolution and large collecting area of the VLA may lead to the detection of the second

ABSTRACT: (U) Shear layers and wakes are a major source of optical degradation in flow lasers. The structure of these flows has been studied experimentally with special attention given to their optical properties. Gases with different refractive indices were investigated and the effects of density ratio and mach number were measured. The time averaged optical properties of inhomogeneous shear layers is reported here wherein the principle far field measurement was the strehl ratio. Modification of the apparatus of the shear is discussed. Keywords: Shear layers, Laser optical degradation, Refractive indices.

ABSTRACT: (U) The ability to adapt to a range of measurement conditions by autonomously configuring software or hardware on-line will be an important attribute of next-generation intelligent sensors. This paper reviews the characteristics of spatial light modulators (SLM) with an emphasis on potential integration into adaptive optical instruments. The paper focuses on one type of SLM, a magneto-optic device based on the Faraday effect. Finally, the integration of the Faraday effect SLM into a laser diffraction particle sizing instrument giving it some ability to adapt to the measurement context is discussed.

ABSTRACT: (U) By measuring the temperature at which molecules begin to spin and by modeling the rotation quantum mechanically, the researchers determined the amount of energy needed to initiate rotation. However, Yates says they do not yet understand the force that prevents spinning at low temperatures and that orients the PF3 molecule in a very specific way relative to the nickel surface. He also notes that if the PF3 molecules are closely packed on the surface, their rotation is strongly hindered by interactions between neighboring molecules, somewhat like interlocking gears.

ABSTRACT: (U) We report a theoretical study of the formation of phenyl radical by attack of a terminal vinyl radical upon a terminal ethynyl group, a reaction of importance in soot nucleation. Structures and energies were computed by the MINDO/3 method with the MOPAC programs. Standard MOPAC options were used for locating the transition structure and for computing force constants and vibrational frequencies. Rate constants for unimolecular isomerizations require an extension of standard RRKM theory. For incorporation into a modeling program the conversion from the open-chain radical (OC) to the phenyl radical (PR) has to be described by a kinetic equation.

SUPPLEMENTARY NOTE: Pub. in Jnl. of Vacuum Science and Technology A, v5 n4 p435-439 Aug 87.

ABSTRACT: (U) High resolution low energy electron reflection measurements and electron energy loss measurements for clean W(100) and for the hydrogen saturated phase (B(1)) on W(100) are reported. The ability to perform both low energy reflectance, low energy electron diffraction, and high resolution electron energy loss experiments on the same crystal using the same electron optics permits several novel experiments. For example, it is possible to quantitatively test the dipole scattering mechanism and examine dipole and impact loss cross sections under precisely defined scattering conditions (i.e., under diffracted beam emergence conditions or at energies corresponding to reflectance resonance conditions). Under certain scattering conditions, the 'dipole' scattering selection rule is shown to break down. Suitable modifications of the electron optics control electronics also permit direct measurements of the cross-section energy dependence of vibrational losses. These new features represent an important step towards quantitative applications of vibrational spectroscopy based on comparing electron energy loss spectroscopy signals from chemisorbed species on different crystal surfaces. Keywords: Surface

ABSTRACT: (U) The interaction of hydrogen with Niobium(100) surfaces has been studied by use of high-resolution electron energy loss spectroscopy, low energy electron diffraction, and work-function measurements. Experimental results indicate that hydrogen adsorbs on Nb(100) at tetrahedral sites below the surface. Hydrogen in these subsurface sites exhibits reversible temperature-dependent effects compatible with the self-trapped subsurface sites proposed to account for the novel kinetics of hydrogen uptake by Nb. Keywords: Chemisorption, Hydrogen interactions with metals hydrogen diffusion; Vibrational spectroscopy.

ABSTRACT: (U) The first crystalline borirene (boracyclopropene) has been prepared by the photochemically induced di-pi-methane-like rearrangement of dimesityl(mesitylethynyl) borane into trimesitylborirene. The structure of the latter compound was confirmed by X-ray crystallography, which showed the central C2B ring as an equilateral triangle, within experimental error, having atom separations of 1.42 Å. The compound is most resistant to oxidation but can be cleaved with glacial acetic acid with the formation of (Z)-1,2-dimesitylethene. The borirene forms a weak complex with pyridines and thereby displays a marked bathochromic shift in such donors. The synthesis of this compound in this novel photochemical way opens up the availability of borirenes and should aid the formation of related, high energy organoboranes and carboranes. Keywords: Organoboranes, Unsaturated boracyclopolyenes, Aromaticity, X ray crystal structure, Boracyclopropenes, Oxidizability, Cleavage, Bronsted acids, Electronic spectral shifts, Boranes.

DESCRIPTORS: (U) *BORANES, *CARBORANES, *CRYSTAL STRUCTURE, *ORGANOBORANES, ACETIC ACID, CLEAVAGE,

ABSTRACT: (U) This article investigates the consequences of departures from independence when the component lifetimes in a series system are exponentially distributed. Such departures are studied when the joint distribution is assumed to follow either one of the three Gumbel bivariate exponential models, the Downton bivariate exponential model, or the Oakes bivariate exponential model. Two distinct situations are considered. First, in theoretical modeling of series systems, when the distribution of the component lifetimes is assumed, one wishes to compute system reliability and mean system life. Second, errors in parametric and nonparametric estimation of component reliability and component mean life are studied based on life-test data collected on series systems when the assumption of independence is made erroneously. In both instances, one may be appreciably misled by falsely assuming independent component lifetimes. The amount of error incurred depends upon the correlation between lifetimes and the relative mean life of the two components. In the modeling problem, the level of reliability and the length of mean system

AD-A189 169

life also affects the error. In the estimation problem sample size may be influential in determining the magnitude of the error. UNCLASSIFIED REPORT

ABSTRACT: (U) This paper considers the problem of
reducing the sensitivity of a possibly infinite
dimensional linear single-input single-output system over
a finite frequency interval by feedback. Specifically the
following are proven: (i) if one wants to bound the
overall sensitivity, the existence of a nontrivial inner
part inhibits the reduction of the sensitivity over the
interval: (ii) in a system that is continuous and has at
most countably many zeros on the imaginary axis, one can
reduce the sensitivity over the interval arbitrarily
small while the overall sensitivity is kept bounded if
and only if the system is outer and has no zeros on the
interval. These extend results for rational transfer
functions.

ABSTRACT: (U) The DOD URIP equipment grant received by the Fuels Combustion Research Group has been used, in accord with the original intent of the award, to update an advance the analytic capabilities of the combustion laboratories. The newly purchased gas and liquid chromatographic instrumentation have become the center pieces of a DOD supported analytic facility that was recently shown to the Chairman of the Joint Chiefs of Staff, Admiral William J. Crowe, Jr. as an example of DOD supported research in the School of Engineering. The chemical analysis instrumentation in the facility as well as the boron particle sizing and visualizing devices that have also been purchased are described briefly in this final report. Photographs of the installed equipment are used to facilitate the description of the various pieces of instrumentation. Keywords: Combustion products, Video equipment; Helium neon lasers.

ABSTRACT: (U) A request was made in response to the DoD/URIP University Equipment Program. At that time, an advanced analytical transmission electron microscope was requested. Following the award of funds, the microscope has been chosen, ordered and is to be delivered shortly. It will be in essence the most advanced microscope of it's kind. The choice of a Philips CM12 was made, since it was felt that this microscope would be able to fulfill the needs of the research effort to which it will be applied. A supplemental report on the performance of this microscope will be made to the technical monitor after some period of operation.

UNCLASSIFIED REPORT

ABSTRACT: (U) Estimating component reliabilities along with the system reliability frequently requires using lifetimes from the system level. Due to cost and time constraints, however, the exact cause of system failure may be unknown. Instead, it may only be ascertained that the cause of failure is due to one component in a subset of components, e.g., the subset forms a subsystem. Confronted with such data, this article discusses how to exploit fully the available information using a maximum likelihood approach. We extend and clarify the useful work of Miyakawa (1984). A small Monte Carlo study indicates the helpfulness of this approach. Keywords: Reliability data bases.

ABSTRACT: (U) Intramolecular cycloadditions of ketenes derived from (o-carbonylphenoxy)acetic acids to carbonyl groups have been utilized for the synthesis of substituted benzofurans. Three methods have been employed to generate ketenes in these systems: (i) Method A: base-promoted elimination of hydrogen chloride from (o-carbonylphenoxy)acetyl chlorides; (ii) Method B: reaction of triethylamine with (o-carbonylphenoxy)acetyl p-toluenesulfonates, (R₂CHC(O)OTs), generated in situ via reaction of (o-carbonylphenoxy)acetic acids with p-toluenesulfonyl chloride; (iii) Method C: reaction of triethylamine with esters generated in situ via reaction of (o-carbonylphenoxy)acetic acids with 2-chloro-1-methylpyridinium iodide (Mukaiyama's reagent). Reaction of triethylamine with (2-formylphenoxy)phenylacetyl chloride (Method A), when performed in the presence of excess cyclopentadiene, afforded the corresponding intermolecular (2 + 2) cycloadduct, 7-(2-formylphenoxy)-7-phenylbicyclo[3.2.0]hept-2-en-6-one, thereby providing independent evidence for the fact that a ketene is indeed generated in this reaction.

ABSTRACT: (U) Several new derivatives of the pentacyclo-undecane system have been synthesized. Thus, diketone 2 could be converted to enone 3 in two ways: (i) in 69% yield via Wadsworth-Emmons reaction with the ylide derived from triethyl phosphonoacetate, and (ii) in 50% overall yield via Reformatsky reaction to afford 4 followed by conversion of 4 to the corresponding mesylate and subsequent DBU-promoted elimination of methanesulfonic acid from this intermediate. Reduction of 3 with sodium borohydride-methyl hydroxide hydrogenation of 3 afforded 6 (88%). Reduction of 6 with NaBH4-MeOH afforded a mixture of lactone 7 (25%) and lactol 8 (40%); presumably 8 is formed via further reduction of 7 with excess sodium borohydride. The structure of 8 was established via dehydration to the corresponding vinyl ether, 9 (79%). Flash vacuum pyrolysis of 7 at 700 C resulted in formation of 1 (25%). This novel reaction constitutes the first example wherein pyrolysis of substituted sigma-caprolactone results in fragmentation with elimination of carbon dioxide and concomitant formation of a substituted cyclopentane.

ABSTRACT: (U) The first single crystal X ray structure of a substituted quadracyclane was reported recently. Surprisingly, two C-C bond lengths in which symmetry considerations suggest should be identical are reported to be nonequivalent. It was suggested that repulsive nonbonded interactions between the carbonyl oxygen atom in the C(1) ester group and the adjacent carbon-chlorine bond, C(7)-Cl, might be responsible for this result. The structure has been redetermined and, in fact, the chemically equivalent bonds are statistically equivalent.

UNCLASSIFIED REPORT

ABSTRACT: (U) This report is a compendium of properties of a mathematical function (the Xi function) which arises in the modeling of turbulent boundary-layer flows near solid walls. The Xi function is formally defined as a triple integral which cannot be easily expressed in terms of elementary or known special functions. Thus series and asymptotic expansions are developed here as well as a table of integrals (most of which are indefinite). The function and its derivative are tabulated correct to ten significant figures. A FORTRAN function routine for the calculation of $Xi(x)$ and $Xi'(x)$ is also given. Keywords: Turbulent boundary layers; Wall layer models; Wall functions.

DESCRIPTORS: (U) *TURBULENT BOUNDARY LAYER, ASYMPTOTIC SERIES, FORTRAN, FUNCTIONS(MATHEMATICS), INTEGRALS, LAYERS, TABLES(DATA), WALLS, MATHEMATICAL MODELS.

IDENTIFIERS: (U) Xi functions.

ABSTRACT: (U) The possible alterations of TCDD toxicity induced by treatments with cytochrome P-450 inducers have been investigated in mice. TCDD toxicity has been evaluated in terms of immunosuppression and hepatic enzyme induction. Drugs able to interfere with the immune response, usually increased the level of inhibition of immune responses when given at the same time as TCDD. Treatment with 3-Methylcholanthrene before or after TCDD always resulted in additive immunosuppressive effect. Similar results were observed in enzymatic studies. In TCDD-TCDF combination when TCDD was given 2 day before and after TCDF, the effect observed in animals treated with both toxins usually was not statistically different from the effects (inhibition of immune parameters or enzymatic induction) caused by the most active compound used in that condition. Time-course experiments were consistent with the conclusion that inducers usually did not modify TCDD toxicity. If inducers had toxic effects by themselves, the effect of combined treatments was the sum of the effect of each drug.

DESCRIPTORS: (U) *DRUGS, *IMMUNOSUPPRESSION, *DIOXINS, ENZYMES, IMMUNITY, IN VIVO ANALYSIS, LIVER, MICE, RESPONSE(BIOLOGY), TOXICITY, TOXINS AND ANTITOXINS.

ABSTRACT: (U) The report describes the first year implementation of the Center for Excellence on Cement Paste Matrix-Composite Materials. Topics include organization and administration, equipment acquisitions, personnel and the development of a comprehensive research program. Preliminary results on projects involving processing of MDF cements and the electrical properties of DSP cements are presented. Keywords: Cementitious materials, Cement pastes, Flexural strength.

DESCRIPTORS: (U) *CEMENTS, *COMPOSITE MATERIALS, *MATRIX MATERIALS, *PASTES, ACQUISITION, ELECTRICAL PROPERTIES, MATERIALS.

IDENTIFIERS: (U) PEB1103F.

ABSTRACT: (U) AM1 calculations for the Cope rearrangements of 1,5-hexadiene (1) and its 2-phenyl (6), 3-phenyl (9), 3-methyl (15), 2,4-diphenyl (10), and 2,5-diphenyl (11) derivatives, via chair transition states, support the Doering biradicaloid mechanism previously predicted by MINDO/3. The relative rates for 1,6,9 and 15 are reproduced closely, the calculated heats of activation being uniformly too large by 3.35 kcal/mol. Larger deviations for 10 and 11 can be attributed to solvent effects and experimental error. The degenerate rearrangements of 1,6, and 11 were predicted to involve 1,5-cyclohexylene biradicaloids as marginally stable intermediates, the lengths of the C1C6 and C3C4 bonds being 1.60-1.65 A. The other rearrangements were predicted to be concerted but not synchronous. Calculations for 1 and 6 with the C1C6 and C3C4 bond lengths set equal to 2.06 A, as expected for a synchronous transition state, predicted retardation by phenyl as predicted by PMO theory. Deuterium kinetic isotope effects calculated for 1,6, and 11 agreed with Gajewski's measurements, within the limits of error of the calculations and experiments.

DESCRIPTORS: (U) *KINETICS, *DIENES, *HEXYL RADICALS, ACTIVATION, CHARRING, DEUTERIUM, ERRORS, ISOTOPES, PHENOLS, RATES, REPRINTS, RETARDATION, SOLVENTS.

ABSTRACT: (U) Two main lines of research were pursued under the support of this grant. The first one was the study of control laws in the presence of many controllers, each of which has his own objective and information, the decisions of each one influence the information and objectives of the others and where the controllers ignore several of the parameters involved in the description of the system equation and objectives. Ideas from both Adaptive Control and Game Theory were combined in developing adaptive schemes for each controller, so that the behavior of the system gets closer and closer, as time goes by to the one that would result in the known parameter case. The second one concerns two more classical game problems including the optimal shooting policy on a target that tries to escape, and the optimal flashing policies of two opponents involved in a duel.

SUPPLEMENTARY NOTE: Pub. in Jnl. of Experimental Brain
Research, v63 p311-350 1986.

ABSTRACT: (U) Because of the purported critical role of cerebellar lobule HVI in classical conditioning of the nictitating membrane response of the rabbit, we recorded extracellularly from HVI Purkinje cells (PCs) during differential conditioning. Rabbits were trained using tonal conditioned stimuli (CSs) and stimulation of the pericocular region as the unconditioned stimulus (US). Many PCs responded to the US, the most frequently observed being a burst of simple spikes. PCs in HVI showed a variety of responses to CSs that were related to the conditioned response (CRs). The most frequently observed response was an increase in simple spikes correlated with CRs. The activity of many of these cells antedated CRs by 20-200ms. A smaller proportion that antedated CRs. The existence of PCs that alter their firing before CRs suggests that they may be causally involved in this behavior, and in this respect they reinforce reports that lesions of HVI or its connections disrupt nictitating membrane CRs. Although complex spike activity was not generally related to the US or to CRs, a few PCs responded in relation to CRs with only complex spikes. In demonstrating CR-related activity in cerebellar PCs, this study supports theories of cerebellar learning such as those of Marr and Albus. Keywords: Cerebellar Purkinje cells; Marr-Albus theory. Reprints.

Statistics, v15 n1 p59-78 1987.

ABSTRACT: (U) A new sieve estimator for the mean function $m(t)$ of a general Gaussian process of known covariance is presented. The estimator $m(t)$ is given explicitly from the data and has a simple distribution. It is shown that $m(t)$ is asymptotically unbiased and consistent (weakly and in mean square) at each t , and that m is strongly consistent for m in an appropriate norm. No assumptions are made about the time parameter or the covariance. Keywords: Consistency; Gaussian dichotomy theorem; Maximum likelihood estimation; Reproducing kernel Hilbert space; sieve.

DESCRIPTORS: (U) *ESTIMATES, HILBERT SPACE, MAXIMUM LIKELIHOOD ESTIMATION, MEAN, REPRINTS, TIME, COVARIANCE, KERNEL FUNCTIONS.

IDENTIFIERS: (U) Gaussian processes, Gaussian dichotomy Theory, *Sieves(Mathematics), WUAFOSR2304A5, PE61102F.

ABSTRACT: (U) The overall objective of the program has been concerned primarily with the processing and characterization of low density and high strength ceramic matrix composites for structural applications. In order to achieve this goal, three main task areas have been emphasized: (i) fundamental studies in processing, (ii) processing of ceramic/metal composites, and (iii) theoretical studies. The work in the first task area consisted of experimental studies on phase transitions in colloidal systems and microstructure/nanostructure evolution during sintering. These studies dealt with the dispersion, consolidation, and sintering of ceramic powders and ceramic forming gels, in an effort to provide a fundamental understanding of key processing parameters that affect the microstructure of the material. The key contribution of these studies has been the recognition of the fact that colloidal consolidated particle compacts display hierarchical clustering due to multiple site nucleation and growth of particle clusters. Consequently, such hierarchically clustered structures display a multimodal void size distribution. The work in the second task area saw development of techniques for processing a new class of particulate based and low density ceramic metal composites composed of boron carbide aluminum and

ABSTRACT: (U) Study of the open-loop forcing of shear layer by a pitching airfoil resulted in three major findings: 1) It is possible to induce very large changes in the shear layer growth rate downstream of the disturbance location, while leaving the portion of the layer between the splitter plate and the disturbance location essentially unaffected; 2) Upstream forcing can be used as a means to modify the shear layer in the region upstream of the disturbance; and 3) Two different mechanisms are responsible for coupling such disturbances to the flow in the cases of upstream and downstream forcing. A separate investigation into the structure of the wake of a pitching air foil in a uniform free stream revealed that the proper choice of the pitch oscillation parameters can result in significant alterations of the wake. In particular, flow regimes corresponding to wake, jet, double-wake and mixed jet-wake structures can be generated. The magnitude of the axial flow along the wake vortices was estimated to increase approximately linearly with both the amplitude and frequency of oscillation. The closed-loop feedback phase of the project was initiated by the successful demonstration of a cancellation experiment in a forced turbulent shear layer. Keywords: Feedback control; Turbulence.

UNCLASSIFIED REPORT

ABSTRACT: (U) Theoretical and experimental research on glassy and crystalline solid electrolytes materials has been pursued. In lithium aluminum silicate we found that the presence of disorder in the aluminosilicate framework can exert substantial effects on the conductivity of the lithium ion; in particular the activation energy for ionic motion is substantially lower in the glassy phase than in the crystalline one, despite the greater disorder in the glass. This was explained in terms of reduced effects of interionic correlation in the disordered material compared to the rigidly alternating crystal. This substantial reduction in the localizing effects of ionic correlations should be operative in all glasses, and may account for enhancements of conductivity in stoichiometric glass compositions at relatively low temperatures. Complex impedance spectroscopy, magnetic resonance, vibrational spectroscopy and differential anomalous scattering techniques have been used to study local structures in silver selenide-germanium selenide glasses. The data seems to show the coexistence of well-defined local order with typical glassy randomness. Diffusion measurements on both uranyl phosphate and beta alumina protonic electrolytes were completed using nuclear magnetic resonance spectroscopy. The results strongly suggest that the simple for the Grotthus mechanism is not operative here. A detailed study of the transport properties of the proton conducting hydrogen-

ABSTRACT: (U) The 1987 Gordon Research Conference on Physical Metallurgy was held 20-24 July 1987 at the Tilton School, Tilton, New Hampshire. The conference topic was Intermetallic Compounds. The primary purpose of the Conference was to bring together three rather disparate groups: scientists and engineers concerned with the mechanical properties of intermetallic compounds, theoreticians interested in the problems of alloy stability and the calculation and prediction of the effects of chemical composition on alloy stability, and engineers interested in developing and producing new alloys based on intermetallic compounds for elevated temperature service. Topics include: Overview Of Strength And Ductility Of Intermetallic Compounds, Dislocation Core Structure and Slip Systems in Intermetallic Compounds, Strengthening Mechanisms in Intermetallic Compounds, Creep and Fatigue of Intermetallic Compounds, Deformation of Non-Cubic Intermetallic Compounds, Overview of Brittle-Ductile Transition Mechanisms, Mechanisms of Ductility Improvement in Lithium, Grain Boundary Accommodation of Slip, Grain Boundary Modelling, Limitations and Approximations of Electronic Structure Calculations, The Thermodynamics of Extended Defects in Intermetallic Compounds, Quantum Mechanics and Fracture.

UNCLASSIFIED REPORT

ABSTRACT: (U) The principal area of our research has been the solution of very large sparse linear programs and linear complementarity problems by successive overrelaxation (SOR) methods. Another important ingredient of our research has been the parallelization of our SOR methods as well as other classical methods such as the simplex method for linear programming and Lemke's method for the linear complementarity problem. A major contribution of our research has been the solution of one of the largest general linear programs ever attempted on a workstation (or in fact on a mainframe). A linear program with 500,000 variables, 125,000 constraints and 1,125,000 nonzero matrix elements was solved in less than 72 hours on one of the Micro Vax II computers. Another significant achievement of our research has been the parallelization of our SOR methods with speedup efficiencies sometimes exceeding 100%. The MicroVax II's were used to test simulations of the parallel SOR algorithms before their implementation on our multicomputers and multiprocessors.

UNCLASSIFIED REPORT

ABSTRACT: (U) This report summarizes accomplishments in the research program presently supported by Grant AFOSR-82-0258 over a period from July 1, 1982 to Sept. 30, 1987, with primary emphasis on the accomplishments from July 1, 1986 to Sept 30, 1987. The basic scope of this program is the analysis, estimation, and control of complex systems with particular emphasis on the development of asymptotic methods and theories for nearly singular systems the investigation of theoretical questions related to singular systems and the analysis of complex systems subject to our characterized by sequences of discrete events. These three topics are described in the three sections of this report. Keywords: Algorithms; Estimates; Detection.

ABSTRACT: (U) Two dye laser systems were purchased for use in energy transfer studies and in unimolecular decomposition experiments. Individual angular momentum states of acetylene in the fourth vibrational state of the CH stretching mode were prepared. It was found that these molecules which contain 10,000 wave numbers of vibrational energy relax at several times the gas kinetic collision rate. There is a striking dependence on the initial rotational state excited implying relaxation of only relatively small amounts of rotational energy. Keywords: Molecular energy transfer, Vibrational energy transfer.

ABSTRACT: (U) The objective of this project is to develop an inelastic electron scattering spectrometer with significantly enhanced capabilities for studying physical and chemical phenomena at surfaces. The instrument combines off-the-shelf commercial instrumentation for sample preparation and characterization with a prototype state-of-the-art high resolution electron energy loss spectrometer (EELS) for studying vibrational properties of surfaces. The capabilities of this new instrument are unique. It extends the application of high resolution electron energy loss spectroscopy to include studies of technical surfaces such as polycrystalline surfaces, disordered thin films and non-single crystal alloy surfaces. Important applications are anticipated including studies of technical surfaces as alloys of aluminum and titanium. The new instrument also extends the range of vibrational spectroscopy studies of single crystals. Detailed tests of scattering selection rules and accurate measurements of the energy and angular dependence of inelastic electron scattering are now possible using the new instrument.

UNCLASSIFIED REPORT

SUPPLEMENTARY NOTE: Pub. in Jnl. of Chemical Society, Chemical Communication, p943-945 1987.

ABSTRACT: (U) The role of nonclassical carbocations has been of major interest to organic chemists for many years. The properties and structures of such ions remain uncertain because of an unfortunate but inevitable lack of experimental data. Very high level ab initio procedures have to be used in theoretical studies of such species if the results are to be meaningful and calculations using such procedures are currently restricted to relatively small molecules. The C3H7+ potential surface is therefore of especial importance because this is the simplest system where the existence of a nonclassical species (protonated cyclopropane) has been established by experiment. Two reasonably high level ab initio calculations have been reported for this system. Both predicted the existence of two nonclassical species, on the ethylene carbenium ion complex, (1)(corner-protonated cyclopropane), the other a species (2) with a three-centre two electron bond (edge-protonated cyclopropane). Both procedures predicted (1) to have C symmetry and (2) to have C2v symmetry, as indicated in the formulae, and both (1) and (2) were predicted to be intermediate in energy between the n-propyl (3) and isopropyl (4) cations. However while one calculation predicted (1) to be lower in energy than (2), the other

EVJ50D

ABSTRACT: (U) The 2-D correlation/convolution which can be achieved in real time via four wave mixing in nonlinear materials has been investigated in detail to determine the accuracy and signal power possible. This analysis was initiated under other support; the experimental confirmation was completed under this contract. The analysis which is based on Fourier transforms of the equations of nonlinear interactions has resulted in a closed form solution for the output and clearly shows how it differs from the desired 2-D correlation. In the example of a scene that is search for given objects, the accuracy decreases as the ratio of scene to object size increases. The accuracy also decreases as the length of the nonlinear material increases resulting in a trade-off between accuracy, size of the scanned scene, and power or signal to noise ratio in the output. The first result of this analysis is the realization that a non-colinear interaction is considerably less accurate than a colinear. In the typical four wave mixing scheme, the two inputs, B1 and B2, propagate at a small angle to each other within a nonlinear medium; the pump wave is counter to one of the inputs. This angle between the beams results in a lateral translation between the patterns as they propagate through the nonlinear material. The result is a correlation between smoothed versions of the inputs and a

ABSTRACT: (U) The synthesis of polybenzazole (PBZ) polymers and model compounds was studied to determine their (1) potential for use in nonlinear optical (NLO) applications and (2) reaction kinetics and chemo-rheology of polymerization in the ordered phase. Specific compounds that should exhibit high figures of merit NLO applications have been identified. The synthesis of PBZ polymers with controlled molecular weight is described, including a description of the synthesis variables important in attaining high intrinsic viscosity and low shear viscosity nematic solutions, leading to improved processability and reproducibility. The phenomenon of mesophase-enhanced polymerization of poly(p-phenylenebenzobisthiazole) (PBT) and the chemo-rheological properties at various shear rates were investigated.

ABSTRACT: (U) The interactions of gallium atoms with silicon (100) surfaces are studied with laser probing. Molecular-beam epitaxy (MBE) is a promising technique for growing high quality, low defect devices, especially those containing complex microstructures. This technique has been particularly useful for growing III-V materials such as gallium arsenide. In the past several years, there has been considerable interest in growing gallium arsenide devices on silicon substrates. However, very little is known about the fundamental interactions of gallium or arsenic beams with silicon surfaces. The present work was undertaken to understand the Ga-Si system better.

ABSTRACT: (U) Collisional J-mixing rates between the $J = 0, 1, 2$ states of the $\text{Sr}(5\text{p sub } J)$ multiplet have been measured in the presence of rare-gas perturbers. For Kr and Xe pressures above 100 Torr, the rates are dominated by a component which is quadratic in pressure. This very unusual behavior is brought about by the simultaneous interaction of a Sr atom with two perturbers and not by excimer formation. Keywords: Energy transfer; Strontium; Reprints.

ABSTRACT: (U) A wealth of ground-based, balloon and rocket measurements of the airglow hydroxyl (OH) emission has been accumulated by various experiments. Indeed, since the first reported rocket observations (HEPPNER and MEREDITH, 1958), there have been over 50 rocket flights from which OH emission profiles have been reported (BAKER and STAIR, 1987). The sensors initially measured in the visible range (PACKER, 1961) and later in the infrared (LOWE, 1960; BAKER, 1978). Models have been constructed of the photochemistry (MOREELS et al., 1977; BATTANER and LOPEZ-MORENO, 1979) and of the vertical species transport in an attempt to fit the measured hydroxyl radiance variations. However, uncertainties exist in quenching rate coefficients, radiation transition probabilities and number densities of participating species, such that results are not conclusive (COXON and FOSTER, 1982; DUPUIS et al., 1986). As part of the overall investigation of neutral atmospheric dynamics of the middle atmosphere and to investigate the excitation processes of the night airglow, a coordinated rocket and ground-based measurement program was conducted as part of the MAP/WINE campaign to observe simultaneously several key parameters.

SUPPLEMENTARY NOTE: Pub. in Pharmacology Biochemistry and Behavior, v27 p143-151 1987.

ABSTRACT: (U) The Morris water task was used to measure the effects of chronic diisopropylfluorophosphate (DFP) treatment on C57BL/6J mice. Control mice showed good task acquisition and searched accurately for the platform after it was removed from the pool, suggesting that they had formed a spatial map of the platform's location relative to distal cues. In contrast, mice chronically treated with DFP prior to training showed a marked deficit in spatial learning. Chronic DFP treatment did not affect ability to locate a visible platform and did not impair task retention in mice trained to find the hidden platform prior to DFP treatment. The chronic DFP treatment decreased muscarinic binding in cortex, hippocampus, and striatum. These results indicate that C57BL mice are capable of spatial learning in the water task. The ability of chronic DFP treatment to impair place but not cue learning suggests that the cholinergic dysfunction produced by DFP is similar to those produced by lesions of central cholinergic systems and acute treatments with muscarinic antagonists. Keywords: Organophosphates; Acetylcholine; Adaptive learning; Reprints.

SUPPLEMENTARY NOTE: Pub. in Experimental Brain Research,
v85 p59-74 1986.

ABSTRACT: (U) The classically conditioned nictitating
membrane (NM) response in rabbit has been widely adopted
for studying learning at both behavioral and
physiological levels (Farley and Alkon 1985; Gormezano et
al. 1983; Moore 1979; Thompson et al. 1976). Recent
evidence indicates that the cerebellum and related
structures are critically involved in the control of this
behavior (e.g., McCormick et al. 1981; Yeo et al. 1985a).
However, a second system, involving reticular formation
in the dorsolateral pontine brain stem (DLP), including
the supratrigeminal region (SR) (Desmond and Moore 1983),
may also participate in the control of CRs (e.g., Desmond
and Moore 1982). To date, there is no evidence of direct
connections between the DLP/SR and components of the
cerebellar circuit, and DLP/SR might therefore be a
circuit that is separate from the cerebellar circuit but
is nonetheless also essential for the NM CR. Previous
investigations have suggested that the dorsolateral
pontine tegmentum (DLP) may be part of a system essential
for classical conditioning of the nictitating membrane
response. The present study examined CR-related firing
patterns of extracellularly-recorded single units in the
DLP. Differential conditioning, using tonal CSs and
periocular electrostimulation as the US, was employed so
that firing patterns on CR and non-CR trials could be
compared. In light of evidence indicating that the
cerebellum is critically involved in conditioning-
cerebellum and the DLP, may be in control of CRs. The

ABSTRACT: (U) The He I photoelectron spectra of NbO and TaO have been recorded. In both cases four main bands were observed which can be attributed to ionization of the isolated metal monoxide molecule. Bands associated with other oxides or the metal were not observed. Assignment of the photoelectron spectra of NbO and TaO was made with the aid of Hartree-Fock-Slater (HFS) calculations and by comparison with the known photoelectron spectrum of VO. The first adiabatic ionization energies of NbO and TaO have been measured as 7.91 + or - 0.02 eV and 8.6 + or - 0.02 eV, respectively. Suggestions are made to explain the poor agreement between previous mass-spectrometric values for the first ionization energy of each oxide. Keywords: Niobium oxide; Tantalum oxide; Reprints; Vanadium oxide.

ABSTRACT: (U) Three aspects of turbulent structure in shear flows were investigated theoretically. Both analytical and computational strategies were employed to extract new information on: 1) advection velocities of large-scale structure; 2) the velocity vector angle characteristics of turbulent fluctuations; and 3) the 'stability' characteristics of the mean turbulent velocity profile. With regard to topic 1, the study of the propagation of a bulge in wall-bounded shear flow has exposed three characteristic propagation speeds. In (temporally and/or spatially) variable pressure flows, a unique inverse approach to the problem has exposed the critical value for the shape factor (H) of 2.0. This result impacts not only turbulent structure dynamics but flowfield separation as well. The work on topic 2, has served to clarify the importance of angular structure with respect to the interpretations of turbulence physics, the modeling thereof and advantages of those variables in numerical simulation. Finally, the mean turbulent velocity profile was found to support unstable modes of oscillation for the large-scale structure if the

ABSTRACT: (U) The He(I) photoelectron spectra of atomic scandium and vanadium have been recorded in the gas-phase. For scandium two bands associated with a 1/4s ionization and one band associated with a 1/3d ionization of the neutral atom have been observed. Measurement of their relative intensities allows the sigma 3d: sigma 4s photoionization cross-section ratio in atomic scandium to be estimated as 57.1 + or - 9.0. In the atomic vanadium spectrum, six bands were seen. Four of these correspond to 1/3d and 1/4s ionizations of the ground state of the neutral atom, the V a 4F state, whereas two bands correspond to 1/3d ionizations of an excited state, the Va6D state, which is approximately 2100/cm above the ground state. Measurement of the intensities of bands arising from the Va4F state allows sigma 3d: sigma 4s to be estimated as 29.8 + or - 2.5 for vanadium. Spectra of vanadium have been recorded with both single- and multi-detector photoelectron spectrometers. Comparison of the data acquisition rates obtained with both spectrometers demonstrates the advantage of using a multidetector instrument in high temperature photoelectron spectroscopy.

ABSTRACT: (U) An inventory whose stock decreases
linearly with time is considered. The inventory may be
replenished at the instants at which a deliveryman
arrives provided that the level of the inventory does not
exceed a certain threshold; deliveries are made according
to a Poisson process. A partial differential equation for
the distribution function of the level of the inventory
is solved to yield a formula for the corresponding
Laplace-Stieltjes transform. The evaluation of the
transform is discussed and explicit results are obtained
for the stationary case.

UNCLASSIFIED REPORT

ABSTRACT: (U) The principal objective of this research program was initiation of the development of a compact, rugged, low-cost, low-power optical synthetic aperture radar processor for real-time image formation aboard airborne and spaceborne platforms. The extremely high computational burden associated with SAR imaging has thus far limited the usefulness of the technique to non-real-time applications from fixed platform bases. Existing real-time digital and optical techniques are in general too bulky, power consumptive, and expensive for broad applicability, particularly in space-confined mobile environments. The integrated optics approach described herein provides a powerful solution with which to circumvent these limitations. The key to this novel optical processing concept is the use of planar optical wave guide technology (which allows the integration of optical components in a single substrate) in conjunction with a time-and-space integrating architecture (which allows two dimensional processing to be performed in a quasi-planar optical structure). An additional novel feature is the utilization of partial waveguide confinement to allow uniform light emission vertically out of the plane of the integrated optical substrate and onto a two-dimensional time-integrating detector.

ABSTRACT: (U) Our aim is to measure the functional neural networks responsible for human goal-directed behaviors. During the past three years we developed new methods for recording and analyzing the electrical activity of the brain while subjects perform simple cognitive tasks. We have sought to determine the feasibility of predicting decrements in performance associated with transient attentional lapses or operational fatigue. Using the method of Event-Related Covariance (ERC) analysis, we found distributed neural preparatory sets that predicted the accuracy of subsequent responses. In a second experiment on the effects of operational fatigue in U.S. Air Force test pilots, we found fatigue-related neuroelectric changes during cognitive processing that preceded appreciable degradations in performance. These results suggest the feasibility of on-line systems that warn of impaired performance due to prolonged mental work by persons engaged in critical or hazardous work.

ABSTRACT: (U) An algebraic structure underlying communications network reliability problems is presented for determining the 2-terminal reliability of directed networks. An iterative algorithm is derived from this algebraic perspective to solve the (s,j)-terminal reliability problem simultaneously for all nodes j. In addition to providing an exact answer (in the form of a reliability polynomial), the algorithm also yields a nondecreasing sequence of approximate solutions guaranteed to be lower bounds on the exact solution. Empirical results, presented for two different implementations of the algorithm, show that useful approximate solutions can be obtained in a reasonable amount of computation time. Keywords: Fortran; Computations.

ABSTRACT: (U) This research program investigates the effect of extreme submicron spatial modulation of the electrostatic potential on the transport in a two-dimensional electron gas (2DEG) in silicon and in III-V compound semiconductor devices. The test vehicle is the so-called grating-gate FET (GGFET). When made to move in a direction perpendicular to the grating gate, electrons experience a surface superlattice (SSL) effect. When moving along the potential modulation electrons are restricted to only one degree of freedom, and thus constitute a quasi-one-dimensional (Q1D) system. Our major achievements in the past year include: In silicon we have fabricated, with high yield, grating gate transistors and measured their current voltage characteristics at liquid helium temperatures. The device mobility at 4 K is about 15000 sq cm/Vs, possibly the highest reported for MOSFETs fabricated using e-beam or x-ray lithographies. Keywords: Surface superlattice, X ray lithography, Deep UV lithography.

ABSTRACT: (U) The deformation mechanisms of aluminum matrix composites containing SiC whiskers or particulate were investigated both experimentally and analytically to determine factors critical to their mechanical behavior. The effects of the discontinuous SiC on age-hardening behavior; the influence of silicon carbide morphology; interactions between SiC dispersoids and matrix precipitates, and dislocations were considered. Two matrix alloys were investigated: a solution-hardened 5456 alloy containing no matrix precipitates; and a 2124 alloy that could be aged and cold worked to contain different matrix precipitate microstructures and dislocation contents. The influence of SiC on the age-hardening behavior of 2124 was evaluated using differential scanning calorimetry. The precipitation sequence in the composites was found to be very similar to that in SiC-free material prepared by either powder or ingot metallurgy. Both whiskers and particulate increased the quench sensitivity of 2124 by causing the precipitation of GPB zones and S' during the quench from solution heat treatment. This effect was independent of quench rate.

UNCLASSIFIED REPORT

ABSTRACT: (U) This program investigated the feasibility of producing degenerate two wave mixing gain in a noninverted resonant medium with local response. According to theory, two wave mixing gain should be possible if the resulting index grating is shifted in space with respect to the intensity grating produced by the two crossed beams. A pulsed molecular beam valve operated at 100 C was used to produce the supersonically cooled I₂ jet. To achieve the moving grating effect, the pump and probe beams were to be crossed in a plane containing the flow axis, with each beam nearly perpendicular to that axis. The pulsed beam valve produced a broad forward peaked distribution of molecules. The velocity distribution at any given point, however, was mainly along the direction of the line joining that point to the nozzle orifice. This was the evidenced by the fluorescence pattern along the laser beam path, which consisted of sharp filaments across the laser beam corresponding to various hyperfine components of a single rotational transition Doppler tuned into resonance with the laser beam at various angles of inclination. Gain in the planned experiment would be observable only within a narrow range of detuning (obtained by crossing the pump and probe beams), and therefore only a small solid angle of the I₂ jet is useful. Various nozzles were tried with the pulsed valve device. Under the best circumstances, an

AD-A188 281

AD-A188 281

UNCLASSIFIED

PAGE 73

EVJ50D

Integrated absorption of only about 10% was measured. With the required angular selection, the expected gain would be on the order of .01%. Since the stability of the laser was such that even after signal averaging a noise of the order of 0.1% remained, it precluded our attempt to demonstrate gain, self pumped, supersonic flow.

ABSTRACT: (U) Based on right-censored data from a lifetime distribution F sub 0, a smooth alternative to the product-limit estimator as a nonparametric quantile estimator of a population quantile is proposed. The estimator is a generalized product-limit quantile obtained by averaging appropriate subsample product-limit quantiles over all subsamples of a fixed size. Under the random censorship model and some conditions of F sub 0, it is shown that the estimator is consistent and has the same asymptotic normal distribution as the product-limit quantile estimator performs better than the product-limit quantile estimator in the sense of estimated mean squared errors.

UNCLASSIFIED REPORT

ABSTRACT: (U) Sliding mode control is examined from the perspective of obtaining stable and robust tracking of an arbitrary time-varying reference by a multi-input-output, linear, time-invariant system driven by a certain class of bounded errors, nonlinearities and disturbances. Most exciting schemes for such systems are subsumed by the one presented here. The results are developed via the use of inverse models, and make clear the constraints imposed by the finite and infinite zero structure of the system. In particular, stable and robust tracking is shown to be obtained by the scheme in this paper if and only if the system is minimum phase. Keywords include: Sliding modes, Variable structure systems, Tracking, Robust control, Inverse models, and Zeros.

DESCRIPTORS: (U) *CONTROL, *SLIDING, *TRACKING,

ABSTRACT: (U) A solution to the problem of detecting and identifying control system component failures in linear time-invariant systems is given using the geometric concept of an unobservability subspace. Conditions are developed under which it is possible to design a causal linear processor that can be used to detect and uniquely identify a component failure in a linear time-invariant system, assuming either i) the components can fail simultaneously, or ii) the components can fail only one at a time. Explicit design algorithms are provided when those conditions are satisfied. In addition to the time domain solvability conditions, the frequency domain interpretation of the results are given, and connection is drawn with the results already available in the literature.

UNCLASSIFIED REPORT

SUPPLEMENTARY NOTE: Pub. in Jnl. of Differential Equations, v68 n1 p10-21, 15 Jun 87.

ABSTRACT: (U) The objective of this paper is to extend the idea of viscosity solution for nonlinear first order Hamilton-Jacobi equations, $u(t) + H(t, x, D(x)u) = 0$ with time-continuous H to time-measurable hamiltonians. We are primarily motivated by the fact that control problems, for which the value function is the viscosity solution of a Hamilton-Jacobi equation, should not be restricted to continuity in time. In Barron and Jensen we were confronted with a linear Hamilton-Jacobi equation arising in the proof of the Pontryagin which had time-measurable coefficients. The existing theory of viscosity solutions did not apply to even this case. Moreover, important models of controlled first order Hamilton-Jacobi equations require time-measurable controls. For example, models of controlled traffic flow or queueing processes might be of this type. We are about then to extend the definition of viscosity solution to generalized viscosity solution applying to time-measurable hamiltonians. In this paper we give the definition and derive the corresponding uniqueness result with an implicit domain of dependence consequent. The fundamental technique used in the proof is the so-called blow up method which has also been used elsewhere, although not in the generality discussed here.

ABSTRACT: (U) Two main lines of research were pursued under the support of this grant. The first one was the study of control laws in the presence of many controllers, each one of which has his own objective and information, the decisions of each one influence the information and objectives of the others and where the controllers ignore several of the parameters involved in the description of the system equation and objectives. Ideas from both Adaptive Control and Game Theory were combined in developing adaptive schemes for each controller, so that the behavior of the system gets closer and closer, as time goes by to the one that would result in the known parameter case. In the optimal shooting policy on a target that tries to escape, and in the optimal flashing policies of two opponents involved in a duel were studied.

UNCLASSIFIED REPORT

SUPPLEMENTARY NOTE: Pub. in Jnl. of Neurophysiology, v57
n6 p1911-1924 Jun 87.

ABSTRACT: (U) Using extra- and intracellular recording techniques, the epileptiform activity in the CA3 subfield of rat hippocampal slices produced by low concentrations of 4-aminopyridine (4-AP) was investigated. At extracellular potassium concentrations between 1-10 millimoles, 5-10 micro moles 4-AP produced spontaneously occurring epileptiform discharges that were associated with an intracellularly recorded paroxysmal depolarizing shift (PDS). The 4-AP-induced PDS appeared to be composed of both inhibitory and excitatory synaptic potentials because of its complex waveform at depolarized membrane potentials. The depolarizing component's mean reversal potential measured using current-clamp techniques was -25.7 mV. Using voltage-clamp techniques, the mean conductance of the depolarizing component was 110 nS with a reversal potential of -14.1 mV. To test the hypothesis that 4-AP was producing epileptiform activity in the presence of normal synaptic inhibition, the effects of 4-AP on mossy fiber evoked synaptic conductances were measured. 4-AP increased the excitatory, early inhibitory, and late inhibitory conductance changes in CA3 pyramidal neurons produced by mossy fiber stimulation. These results suggest that the epileptiform activity produced

AD-A188 229

AD-A188 229

UNCLASSIFIED

PAGE 80 EVJ50D

by 4-AP is, at least in part, a consequence of enhanced inhibitory and excitatory synaptic transmission and that epileptiform activity can occur without impairment of synaptic inhibition.

ABSTRACT: (U) Professor Kahan pursued research to provide improved subroutines for common arithmetic functions for scientific computations. He produced an algorithm for the accurate implementation of rational arithmetic operations without resorting to multi-precision arithmetic. This was described in a paper entitled Rational arithmetic in floating point. He has also made a careful study of how to make branch cuts in the complex plane so as to allow evaluation of the elementary functions without any anomalies. This was presented in a talk at the conference on State-of-the-Art in Numerical Analysis held in Birmingham, England, April 14-18, 1986. Keywords: Computations.

UNCLASSIFIED REPORT

ABSTRACT: (U) Mental workload has been very difficult to describe quantitatively. An excessive workload can lead to a decrease in accuracy and performance, while a sustained high level of workload can lead to mental exhaustion. Previous research has indicated that heart rate variability and evoked potentials in the EEG (electroencephalogram) may be linked to mental workload. Unfortunately most of the work to date has examined these two biocybernetic variables independently rather than jointly. Recent advances now allow one to measure the magnetic fields produced by the brain (MEG) using a SQUID magnetometer (Superconducting Quantum Interference Devices). Much of the MEG research to date has concentrated on lower order brain processes rather than the higher cognitive processes associated with workload. The current research examines all these biocybernetic variables jointly in an effort to quantify mental workload. A paradigm was developed to vary several aspects of mental workload and verify the hybrid capacity model of human information processing that was developed at Purdue. This research included constructing a data acquisition system to implement this paradigm and simultaneously record heart rate, respiration, EEG & MEG data. It is believed that this is the first time that such a varied data set was recorded simultaneously.

ABSTRACT: (b) The memory organization and technological design parameters which create memory access conflicts and affect performance of the CRAY family of processors are studied. Measurements on the dynamic-memory CRAY-2 system are presented.

UNCLASSIFIED REPORT

ABSTRACT: (U) The Center for the Study of Rhythmic Processes began operation in the academic year 1986-87. It brought together mathematicians and biologists to work on problems of mutual interest. During the first year, the Center focused on two sets of problems. The first involved the structure and function of the intersegmental coordinating system of the vertebrate spinal cord, for which the lamprey provides an excellent model system. A broadly applicable mathematical framework was constructed for analyzing this system, and new mathematical techniques were invented. A new technology was put into use which has the potential of providing information not previously obtainable. Many of the major researchers working on this preparation were consolidated under the auspices of the center, and many new collaborations were formed. The other involved small neural networks, such as the stomatogastric ganglion of the lobster. Detailed mechanisms of function and control were investigated, and mathematical tools were applied to investigate how the circuits change under modulation. Keywords: Oscillators; Regeneration; Central pattern generators; Mathematical modeling; Sensory feedback; Neural networks; Neuromodulators.

UNCLASSIFIED REPORT

ABSTRACT: (U) In the present investigation, the effects of dispersed SiO₂ particles on the high temperature oxidation behavior of and alloys were studied. This study differs from previous investigations in that larger volume percents of SiO₂ (5-40 vol%) were incorporated into the alloys. Kinetic studies were done using an automatic recording semi-micro balance under the desired conditions (1 atm O₂ and 1273, 1373, 1373K). Surface topographies of oxidized specimens were also prepared and examined optically and by scanning electron microscopy. Standard x ray diffraction techniques were employed to identify the phases present in the scale. Based upon extensive results obtained for the Ni-Cr-SiO₂ alloy a model for oxide formation in this system is proposed. The results obtained for the Fe based system will also be presented in this report.

UNCLASSIFIED REPORT

ABSTRACT: (U) The following describes the results of research on III-V molecular beam epitaxial (MBE) growth, material characterization and the fabrication of heterostructure bipolar transistors (HBT) for very-high-speed logic applications. Work on the InGaP/GaAs heterojunction (HJ) was completed. Isotype HJs were grown and evaluated by a CV reconstruction method in order to determine the energy band offsets. It was found that $\Delta E_c = 0.22$ eV and $\Delta E_v = 0.24$ eV for the lattice matched composition. An inverted AlGaAs/GaAs HBT was investigated, and it was shown that an undoped, graded region between emitter and base would eliminate the conduction band spike and provide a buffer for Be diffusion. A new direction toward improvement in performance and fabrication techniques for the AlGaAs/GaAs HBT was successfully demonstrated. Graded-bandgap nonalloyed ohmic contacts using n⁺ InAs for the AlGaAs emitter and p⁺ GaSb for the GaAs base were provided by selective epitaxial regrowth. The MBE growth conditions for grading from GaAs to InAs and GaAs to GaSb were determined. Low specific contact resistances were observed for both contact types. A self-aligned AlGaAs/GaAs HBT with graded-gap contacts to both base and emitter was demonstrated.

ABSTRACT: (U) This project supported an investigation into extending a relational system to support new kinds of data objects such as lines, points, polygons, bit maps, text, documents, vectors and arrays. Two important tactics were studied: 1) use of an abstract data type system (ADT); and 2) use of procedural objects. Basically an ADT system allows new data types to be added to a relational system to augment the normal character strings, integers and floating point numbers traditionally provided. In addition, procedures provide a powerful data modeling capability that is especially useful for complex objects or objects that have unpredictable composition. The important results that the authors achieved are twofold. First, they obtained results on the integration of an ADT system into a general purpose DBMS. In particular, they discovered how to integrate new data types with query optimization routines and how to allow new access methods to be constructed for the new data types. Second, they designed a syntax for efficient manipulation of procedural objects and then constructed query optimization algorithms to efficiently process this extended syntax.

ABSTRACT: (U) This report summarizes the work performed on a three year program to obtain an understanding of deposition processes of thin films from plasmas. Deposition plasmas of methane and of methane-hydrogen and methane-silane mixtures were characterized via electrical, optical, and mass spectroscopic measurements. Surface chemical studies of the fundamental surface reactions were performed, and a model was constructed which takes into account both gas phase and the surface processes leading to deposition. The properties of the deposited films were related to the plasma conditions associated with their deposition. Advances in process modeling and surface chemical techniques were achieved on this program, in addition to the knowledge that was gained about the specific plasma deposition processes that were studied.

ABSTRACT: (U) Solid solution strengthening of GaAs by In atoms acting as InAs 4 units has been predicted for an intermediate temperature, plateau region. This strengthening could partially account for the reduction in dislocation density in crystals grown from the melt. Deformation studies of undoped and In-doped (1-2X 10 to the 20th atoms/cc-3 GaAs were performed in compression in the temperature range 500 - 1100 C at a strain rate of .0001/s in both multiple slip, 001, and single slip. 123, orientations. The critical resolved shear stress is nearly doubled with indium additions, but both undoped and In-doped materials show a weakly temperature independent critical resolved shear stress, expected from the solid solution strengthening model. The results also showed that the onset of dynamic recovery occurred at higher stress and strain levels for the In-doped materials, suggesting that the climb process is more difficult in these alloys.

EVJ500

ABSTRACT: (U) The rigorous connection between viscosity solutions for the Bellman equation in optimal control and the Pontryagin Maximum Principle has been established. The method developed for controlled ordinary differential equations was extended to infinite dimensions to derive the Pontryagin principle for 1) a class of controlled nonlinear evolution equations in a Hilbert space, 2) a class of controlled nonlinear, divergence form parabolic partial differential equations; and 3) a class of differential-difference equations. Additional subjects were studied were the extension of the idea of viscosity solution to equations with only time-measurable Hamiltonians and the optimal cooling of a free boundary problem with Stefan problem dynamics. Two problems of interest in specific applications were solved. The optimal control is characterized in the class of monotone functions which minimizes the H1 distance to a given function. This problem, a specific monotone follower problem, arises in production planning. An optimal portfolio selection problem is considered which includes stock, options, bonds and borrowed cash at an interest rate different from the bond interest rate. This problem is formulated using stochastic optimal control and explicitly constructed the solution of the Bellman equation. The objective of the study was to derive the

ABSTRACT: (U) The reactions of SiH₂ (generated from the disilane pyrolysis with ethylene and with butadiene have been studied by the comparative rate technique. Ethylene trapping of silylene is a consecutive step process involving the formation of a silacyclopropane intermediate which can react back to reactants or forward to either ethylsilylene or vinylsilane. Reaction products of ethylene trapping vary with reaction conditions. At high reactant concentrations and low temperatures the main product is ethylsilane, but numerous other products including diethylsilane and ethyldisilane are also formed. At low reactant concentrations and moderate temperatures the main products are ethylsilane and vinylsilane, while at high temperatures vinylsilane is the only significant product. A number of rate constants and rate-constant parameters for the relevant reactions of the proposed rather complex mechanism have been estimated by using a variety of data sources. Keywords: Kinetics, Silylene disilane, Ethylene, Butadiene, Silacyclopropanes.

UNCLASSIFIED REPORT

ABSTRACT: (U) This report investigated fundamental aerothermal phenomena in hypersonic flow, with particular emphasis on viscous/inviscid interaction phenomena. The experimental studies were conducted to examine the changes in the structure at the base of a hypersonic turbulent boundary layer as it is subjected to a strong self-induced pressure gradient in regions of shock wave/boundary layer interaction. The initial phase of the theoretical program was directed toward summarizing existing techniques for obtaining Navier/Stokes solutions for laminar flow over flat plates in hypersonic flow. In the experimental program, surface and flow field measurements were made to examine the detailed flow mechanics associated with turbulent boundary layer separation over a large cone flare model at Mach numbers 11, 13 and 16 and Reynolds numbers up to 100 million. Holography measurements were used to examine the flow field regions of hypersonic shock wave/turbulent boundary layer interaction. In this preliminary investigation of the application of holography in a 96 inch Shock Tunnel, holographic interferograms were obtained for viscous/inviscid interactions at Mach numbers 11 and 13 and Reynolds numbers up to 30 million, nominally. Flow field

studies were made for flat plate/wedge, cone/flare and incident shock configurations. The quantitative results presented offer new information as well as a potential to obtain density measurements in other types of hypersonic flow; however, they also reveal important concerns which need to be resolved before the interferometric data can be claimed to give accurate measurements of these flows. Two appendices include an invited review paper on aerothermal problems associated with hypersonic flight.

ABSTRACT: (U) The main tools for the prediction of convective radial mixing are developed. The secondary flows needed for the convective mixing are found from pitch averaged vorticity equations combined with integral methods for the computation of 3d end-wall boundary layers, 3d profile boundary layers and 3d asymmetric wakes. This integral approach requires less approximations than previous radial mixing theories and only three empirical constants are required. The convective mixing coefficient of Adkins and Smith is found from the resulting secondary flow velocities. The method is applied to some standard test cases, where secondary flow patterns are compared with available test data.

EVJ50D

ABSTRACT: (U) Research on new semi-insulating behaviour in III-V compounds completed the determination of electronic levels and related optical properties of substitutional titanium in bulk grown InP and GaAs. In the course of the corresponding crystal growth study we have also identified impurity gettering by transition elements. This gettering takes place due to melt (or solution), and it can be beneficial or detrimental for obtaining Si materials. An example of the beneficial role is provided by the interaction of vanadium with silicon, which reduces Si donor concentration in the grown crystal. An example of detrimental effect is provided by the interaction of titanium with carbon, which reduces the concentration of deep compensating Ti donors in epitaxial or melt grown crystals. Appropriate redesign of the epitaxial growth cell (eliminating all graphite elements in contact with the solution) is in progress. An investigation has been carried out on the extension of liquid phase electroepitaxy to the growth of bulk InGaAs crystals. We have successfully developed procedures for the electroepitaxial growth of InGaAs ingots 14 mm in diameter and up to 3 mm thick. To our knowledge, these are the first bulk InGaAs crystals to show excellent compositional uniformity (in accord with theoretical predictions for electroepitaxy).

SUPPLEMENTARY NOTE: Prepared in cooperation with Syracuse Univ. NY. Dept. of Mechanical and Aerospace Engineering.

ABSTRACT: (U) The characterisation of the nozzle guide vane inlet and exit conditions in the Oxford University Isentropic Light Piston Tunnel fully 3-D annular rotating stage has been undertaken. Measurements included hot wire anemometry and pressure/Mach number distributions. Preparations for the rotor heat transfer instrumentation/data acquisition hardware and software are also in progress. Further development of a numerical model to predict the effects of wake passing and transition is reported. The convection of the wake through the passage is predicted, allowing for estimations of the expected times for which the boundary layer is disturbed by the wake fluid. The new model for the random generation and subsequent growth and convection of the turbulent spots produces a time-resolved prediction of the intermittent heat transfer signals by use of a time-marching procedure. By superimposing the two numerical models it is possible to simulate the measured instantaneous heat transfer characteristics and to estimate the effective average intermittency along the blade surface and compare the results to the measured intermittency values.

ABSTRACT: (U) The principal objective of this research program was initiation of the development of a compact, rugged, low-cost, low-power optical synthetic aperture radar processor for real time image formation aboard airborne and spaceborne platforms. The extremely high computational burden associated with SAR imaging has thus far limited the usefulness of the technique to non-real-time applications from fixed platform bases. Existing realtime digital and optical techniques are in general too bulky, power consumptive, and expensive for broad applicability, particularly in space-confined mobile environments. The integrated optics approach described herein provides a powerful solution with which to circumvent these limitations. Keywords: Optical information processing, Optical computing, Integrated optics, Guided wave optics, and Synthetic aperture radar.

ABSTRACT: (U) In this program, low pressure flames of hydrogen and hydrocarbons burning in fluorine are studied by measuring ionization, luminescence and laser induced fluorescence of intermediates. Oscillatory and pulsing behavior are noted in these flames. Experiments are designed to establish the mechanism of CH A-state emission in oxygen free combustion. Theoretical consideration of the long time behavior of bimolecular reactions has provided a general endpoint indicator for chemiluminescent gas phase titration reactions as well as a means of measuring rate constants for reactions such as H + F combination. ABSTRACT: (U) The goal of this research is to produce quantum limited SIS quasiparticle heterodyne receivers at submillimeter wavelengths. The approach is to compare the performance of waveguide and planar lithographed quasi-optical SIS mixers in W-band (lambda approx. 3mm) in order to understand the factors which upgrade the performance of the latter. This information will be used to optimize the planar quasi-optical mixers. Finally, these optimized designs will be scaled to submillimeter wavelengths. Systematic tests of both types of mixers have been carried out during the second grant year. Improved designs of planar quasi-optical mixers have been designed and fabricated. The construction of test apparatus for submillimeter wavelengths has begun.

ABSTRACT: (U) Billingsley developed a widely used method for proving weak convergence with respect to the sup-norm and J-Skorohod topologies, once convergence of the finite-dimensional distributions has been established. Billingsley's method works not only for J oscillations, but also for M oscillations. This is done by identifying a common property of the J and M functions, called sub-triadditivity, and then showing that Billingsley's approach in the case of the J function can be adequately modified to apply to any sub-triadditive function. Keywords: Weak convergence; Skorohod topologies; Sub-triadditivity.

ABSTRACT: (U) Human observers have difficulty detecting acceleration in a moving visual image. If observers are shown two briefly-presented (100 msec) moving targets, one after the other, they can learn to discriminate a 6% difference in their velocities. If instead, a single target is presented moving at one velocity (reference velocity), which abruptly changes to a new velocity of 100 msec, and then returns to the initial velocity, a difference of 6% is virtually undetectable. Even when a jerk or perturbation in the trajectory is detected, observers frequently have difficulty saying whether the target increased or decreased its velocity. In short, the reference velocity is masking the incremental change. A number of experiments were performed to explore the influence of velocity, spatial extent, and trajectory discontinuities on masking effect. Keywords: Target recognition; Target discrimination; Moving target indicators.

UNCLASSIFIED REPORT

ABSTRACT: (U) Progress over the past year has been rapid and wide ranging, covering two primary areas. First, in the area of visual attention, we have shown both the existence of a sustained and a transient component of enhanced pattern recognition. This cannot be explained by visual transients or eye movements. Second, we have examined a wide range of issues related to partial visibility (occlusion) using stereoscopic displays. In particular, we have shown that pattern recognition of partially hidden objects is superior if the pattern is in a rear vs. front stereoscopic plane, that the solution to the aperture problem for motion is dictated by whether line terminators are seen as real terminators or the result of occlusion by other surfaces, and finally, we have shown that the depth interpretation of untextured stereograms requires that the visual system edges before evaluating their depth.

EVJ50D

ABSTRACT: (U) A nonlinear theory of turbulent coherent structures near walls has been developed based on the assumption that the eddies are flat, with large horizontal dimensions compared to their thickness. Turbulence in the outer part of the boundary-layer may be modelled as a linearly driven system with nonlinearities confined to the near wall region. A new model for near wall turbulence based on the concept of an instantaneous mixing length gives a mean velocity profile valid from the wall to the beginning of the log region. The effect of Large Eddy Break-up devices on the boundary layer was modelled as a wake deficit. The wake acts as a barrier to structures crossing the wake. Measurements of the skin friction behind LEBU's using a variant of the Stanton tube are in agreement with other techniques. Keywords: Turbulent boundary layer; Boundary layer control; LEBU(Large Eddy Break Up); Eddies(Fluid Mechanics), Structural properties; Boundary layer transition; Active walls; Flexible structures; Shear stresses; Drag reduction.

DESCRIPTORS: (U) *BOUNDARY LAYER CONTROL, *TURBULENCE, *TURBULENT BOUNDARY LAYER, BARRIERS, BOUNDARY LAYER, BOUNDARY LAYER TRANSITION, CROSSINGS, DEFICIENCIES, DRAG REDUCTION, FLEXIBLE STRUCTURES, FLOW, HORIZONTAL ORIENTATION, LENGTH, MEAN, MIXING, MODELS, NONLINEAR

UNCLASSIFIED REPORT

ABSTRACT: (U) The role of adenosine in sleep has been further investigated using electroencephalography to document the dose response effects of newly developed specific adenosine A1 and A2 receptor stimulants and 8-cyclopropyltheophylline (CPRT), a substituted xanthine. The results with adenosine agonist suggest that both A1 and A2 receptors play a role in the hypnotic action of adenosine. The data with CPRT point out that stimulant effects of xanthines is obtained by the blockade of A1 receptors. Desensitization of adenosine A2 receptors was found following the chronic treatment of adenosine agonists L-PIA, NECA and deoxycoformycin. Chronic administration of caffeine up-regulates A1 receptors in cerebral cortex in a manner similar to that following deprivation of REM sleep. This suggests the existence of an endocaffeine whose normal role is to block adenosine receptors during prolonged sleep deprivation- a mechanism that could be responsible for the increased number of adenosine receptors. Keywords: Hypnosis; Physiological effects; Sleep deprivation.

ABSTRACT: (U) An important task in the evaluation of a communication or distribution system is assessing the performance of the system, when its components are subject to random failure. One approach for approximating various such performance measures is to generate a relatively small set of states of the system that covers in probability a large portion of the probabilistic system in order of nonincreasing probability. Rather interestingly, there is an elegant algebraic structure (a lattice) underlying this problem, and this structure can be exploited to produce a relatively effective algorithm for generating in order the states of the given system. In addition, the worst-case computational complexity of the algorithm is shown to be related to a certain algebraic invariant of the lattice.

ABSTRACT: (U) The role of brain cholinergic receptors in regulation of physiological and behavioral function was examined by inducing a change in the number of muscarinic cholinergic receptors and studying the effects of these changes on tolerance development and spatial learning in inbred mice. Chronic treatment with oxotremorine caused a down regulation of receptors in five brain regions including hippocampus and cortex, regions thought to mediate spatial learning. The time course of receptor recovery was compared to the loss of tolerance and changes in spatial learning ability. While receptor numbers were decreased for as long as 4 days after cessation of treatment, tolerance to oxotremorine was only detected for 48 hrs after removal from chronic treatment. Like wise, impairment of spatial learning was evident when animals began training at 24 hrs after cessation of treatment but learning was normal by 48 hrs after treatment. These results indicate that the status of cortical and hippocampal cholinergic function may be important for initial behavioral effects, but that there must be other factors in addition to receptor number that are important in the regulation of physiological and behavioral function. The possible roles of other cholinergic markers and other neurotransmitter systems are currently being investigated including NMDA receptor

ABSTRACT: (U) In this quarter, we conducted a performance evaluation of the proposed optical architecture SPARO (Symbolic Processing Architecture in Optics). Specifically, we examined the performance of the ring interconnection network of SPARO. An accurate performance model was developed for predicting the message throughput of bidirectional ring network. As suspected earlier, the ring network was the bottleneck in the performance. This led us to study other network topologies that are both feasible in optics and yield high throughput. The final choice of the optical interconnection network topology was deemed by the replicated perfect shuffle network.

ABSTRACT: (U) The p-Version of the finite element method
has been previously analyzed for elliptic problems with
homogeneous boundary conditions. For a homogeneous
condition of the Dirichlet type, it was shown that the
exponential asymptotic convergence rate was optimal up to
an arbitrarily small positive parameter epsilon. In this
paper, an alternate proof is discussed which yields a
better estimate by removing the dependence on epsilon.
The analysis is extended to treat problems with
inhomogeneous boundary conditions of both the Dirichlet
and Neumann type. Estimates for a case when the solution
has singularities at the corners of the domain are also
provided. Keywords: Approximation(Mathematics);
Polynomials.

ABSTRACT: (U) New results in the extension of maximum
principles to systems using best possible estimates were
the high light topic. These apply to equations in
continuum mechanics.

ABSTRACT: (U) Major achievements from this research project include the preparation and characterization of new types of dialkylaminophosphorus derivatives and their metal carbonyl complexes. Reductions with LiAlH₄ of dialkylaminodichlorophosphines, R₂NPCl₂, having sufficiently large dialkylamino groups were found to lead to the corresponding dialkylaminophosphines, R₂NPH₂ (R₂N = dicyclohexylamino and 2,2,6,6-tetramethylpiperidino) as very air-sensitive liquids. Dehalogenation of R₂NPCl₂ (R = isopropyl or cyclohexyl) with magnesium in tetrahydrofuran was found to give the corresponding cyclooctaphosphines (R₂N)P₄; the corresponding biphosphines (iPr₂N)P₂X₂ (X = Cl and Br) can be isolated from reactions of iPr₂NPX₂ with more limited quantities of magnesium. Keywords: Phosphorus, Silicon, Boron, Metal complexes, Dialkylamino, Cyclopolyphosphines, Metal carbonyls.

ABSTRACT: (U) The authors consider a finite horizon control model with additive input. There are two convex functions which describe the running and the terminal costs within the system. The cost of input is proportional to input and can take both positive and negative values. It is shown that there exists a deterministic control problem whose optimal cost is the same as the one in the stochastic control problem. The optimal policy in the stochastic problem consists of keeping the process as close to the optimal deterministic trajectory as possible. Keywords: Stochastic linear systems; Additive noise; Optimization.

ABSTRACT: (U) This report summarizes work done by the author during the past twelve months on the dynamics of complex rotating systems. Our recent work on the mechanics of rotating elastic structures shows a complex dependency of asymptotic equilibrium states on physical parameters such as elasticity of the material and total momentum of the structure. For multiply articulated rigid bodies undergoing large angle rotations, it is shown explicitly how there can be a sensitive dependence of equilibrium states on parameters of inertia and angular momentum. This suggests that recent work on geometrically nonlinear beam theories may be significant not only for transient analysis, but for accurately modeling asymptotic dynamics as well. Keywords: Classical mechanics, Beam theories, Equilibrium dynamics, Kinematic chains.

ABSTRACT: (U) The absolute rate constants for the cycloaddition reactions of three arylhalocarbenes to two alkenes have been measured as a function of pressure in the range 0.1 to 203 MPa. In all cases the observed rate constants were found to increase with increasing pressure. The magnitude of the derived activation volumes falls in the range of -10 to -18 cc/mol and does not depend on solvent. The results rule out a late, two-bond transition state and a bipolar single-bond transition state, but are consistent with the reversible formation of a carbenealkene complex or an early one- or two-bond transition state. EVJ500

ABSTRACT: (U) A direct pole relocation theory is advanced for linear time-invariant systems with distributed delays in both state and control variables. The principal tools of the theory include 1) the finite cardinality of the unstable spectrum; 2) a set of matrices, each of which is left zero of the system characteristic quasi-polynomial matrix; and 3) a linear transformation which reduces the delay system to a sufficiently high-order delay-free system whose spectrum contains the delay system unstable spectrum. It is shown that if the system is spectrally stabilizable, then it shares a common feedback stabilizing control law with its delay-free counterpart. This point of contact with a delay-free system permits the determination of the control law using well-established ordinary system methods. The workability of the approach hinges on the ability to partition the unstable spectrum (augmented with additional poles from the stable spectrum, if necessary) into N symmetric sets. When this partition is impossible, a spectral controllability invariance theorem facilitates resolution of the problem. Keywords: Reprints; Matrix equations.

ABSTRACT: (U) The Pontryagin Maximum Principle is proved for the Lagrange problem of optimal control using the fact that the value function of the problem is the viscosity solution of the associated Hamilton-Jacobi-Bellman equation. The proof here makes rigorous the formal proof of Pontryagin's principle known for at least three decades.

ABSTRACT: (U) This paper considers the question of well-posedness for a functional differential equation (FDE) that has been used to mathematically model the elastic motions of a two-dimensional airfoil in unsteady flows. This equation is a neutral functional differential equation (NFDE) for which the D operator is not atomic at $s=0$. Equations of this type also occur in the theory of lossless transmission lines and include many singular integrodifferential equations. It is often advantageous to have a state space model for these systems when addressing certain numerical and control problems. Section 2 presents a brief summary of recent results concerning necessary and sufficient conditions for neutral equations to be well posed in product spaces. Section 3 considers the well-posedness question for the aeroelastic model and close with a discussion of more general equations. Keywords: Reprints, Aeroelasticity.

UNCLASSIFIED REPORT

ABSTRACT: (U) Multigrid has become an important method for the solution of discrete elliptic equations. However, there is much to be done in the theory of convergence proofs. At the present time there are two general two-level methods for general convergence proofs: an algebraic approach and a duality approach. While these theories do not give sharp estimates, they provide good, general, rigorous convergence theorems. This note studies the relationship between these theories. While the approach and thought process leading to these theories are different, the results are essentially the same. Indeed, the basic estimates required by these theories are the same. Keywords: Reprints; Convergence.

DESCRIPTORS: (U) *CONVERGENCE, *ITERATIONS, ALGEBRA, ELLIPSES, EQUATIONS, ESTIMATES, REPRINTS, THEOREMS, THEORY.

IDENTIFIERS: (U) Discrete elliptic equations.

SUPPLEMENTARY NOTE: Pub. in Jnl. of Physical Chemistry, v91 n17 p4544-4548 1987.

ABSTRACT: (U) The effects of additives on the recombination efficiency and exit rates of micellized benzyl radicals have been studied by steady-state CIDNP, steady-state product analysis, and time-resolved optical absorption techniques. The results indicate that the efficiency of triplet geminate pair recombination increases monotonically as the micellar volume increases. Aggregation numbers of SDS micelles were deduced as a function of additive concentration from CIDNP measurements and were found to be consistent with literature values. Keywords: Time resolved absorption; micelles.

ABSTRACT: (U) A study of the spectroscopic and laser properties of the crystal erbium and chromium-doped yttrium scandium gallium garnet (Er,Cr:YSGG) has been carried out. The absorption spectra from 300-1700 nm and the emission spectra in the regions around 800, 1600 and 2800 nm have been measured, along with the kinetics of emission and decay under pulsed excitation. Energy levels of the erbium ion have been determined. Analysis of the data shows that energy transfers from excited chromium ions to erbium ions with near-100% efficiency. The 2800-nm-region laser performance of Er,Cr:YSGG, under flashlamp pumping conditions has been observed and found to be superior in some aspects to other erbium doped crystals.

UNCLASSIFIED REPORT

ABSTRACT: (U) This report describes a pumped dye laser system used in studies of the combustion of nitramine based solid rocket propellants. Although these propellants have advantages of high specific impulse and low infrared and smoke emissions from their exhaust, better control of the burn rate is needed. Propellant additives have been suggested for burn rate control but the understanding of the chemical mechanism of burning is not well enough developed to predict the effects of these burn rate modifiers. The objective of our studies is to describe the detailed chemistry of reactions of gas phase species which are important in the combustion of nitramine propellants and additives. Species composition, temperature and burning rate have been measured for reacting gas mixtures representative of the pyrolysis products of nitramines and nitramines with additives. Chemical kinetic and fluid mechanic modeling of the flame structure is used to correlate the experimental data and evaluate critical reaction paths and energetics and their importance in burn rate control.

UNCLASSIFIED REPORT

ABSTRACT: (U) This report summarizes the results on chemically reacting turbulent flow. The development of new diagnostics for variable density flows are described. These include Rayleigh light scattering for real-time, spatially-resolved concentration measurements, combined Rayleigh light scattering and hot wire anemometry for simultaneous concentration and velocity measurements, and the development of a digital line camera which has allowed the concentration measurement to be made along a line. A study of heat transfer from heated cylinders is discussed which has generated a much improved correlation of experimental results. Shadowgraph visualization studies and centerline concentration measurements are described for variable density, axisymmetric turbulent jets covering jet to coflow density ratios of 0.14 to 37. These studies have also included a limited investigation of Reynolds number effects. The observed dependence of the mixing behavior on the density ratio and Re have led us to make new hypotheses are shown to lead to qualitative predictions for the turbulent mixing which are in agreement with experimental findings.

ABSTRACT: (U) Several directions have been followed toward the attainment of our research goals. We have continued recording in the untrained monkey, looking at arousal related changes in spontaneous and evoked thalamic activity, as well as, the effects of various drugs on these responses. We are now recording the responses of thalamic somatosensory neurons in behaviorally trained animals, looking at response modulation during two attentional paradigms, including shifts in arousal. Preliminary experiments have been conducted to develop methods for examining the underlying mechanisms of thalamic modulation. We are continuing to update and validate our computerized stereotaxic atlas of the green monkey brain. We have also developed a unique computer program for the acquisition (PETH) and statistical analysis (HISTSAT) of perievent time histograms. Some of the results in this report have been or will be communicated at scientific meetings, published or are in press. Keywords: Nerve transmission, Cerebral cortex.

MONITOR: AFOSR
TR-87-1681

UNCLASSIFIED REPORT

ABSTRACT: (U) Attentional models offer alternatives for describing blocking, overshadowing, and many other features of classical conditioning. Two such models emphasize variations in the associability of CSs instead of variation in the effectiveness of the reinforcing event, the US. Early published variants do not always accurately portray the effects of nonreinforced CS presentations as represented in simulation experiments. In one case levels of conditioned responding under partial reinforcement are too low to reasonably approximate expectations based on the experimental literature, and extinction is too deep to produce the rapid reacquisition that typically follows extinction. These problems are corrected by changing the expressions in the model for decreasing associative strength. The revised model retains the positive features of the original, e.g., the ability to stimulate in real-time latent inhibition and compound CS effects such as blocking and conditioned inhibition. The other model is path dependent and highly nonlinear under partial reinforcement. The problem can be corrected either by modifying and restricting the rules for computing the associability of the CS, or by modifying the rules for computing associative strength. The revised model retains the original's ability to simulate latent inhibition, compound CS effects, and the transfer (positive or negative) from training with a weak US to training with

UNCLASSIFIED REPORT

ABSTRACT: (U) After studying soot formation in normal diffusion flames, near and slightly sooting inverse diffusion flames were investigated to determine the key intermediates to soot formation. The results indirectly confirm that the initial number density of soot particles which form scale with aromatic formation just prior to soot inception. Correlations exist between a fuel's sooting tendency as measured by the Princeton smoke height experiment and the extent of aromatic formation measured in both inverse and normal diffusion flames. Work on the oxidation of the aromatics present in jet propulsion fuels continues with th major effort directed at the alkylated benzenes. The major study concerned the oxidation of para-xylene. The results indicate oxidation of one side chain at a time before the benzene ring is attached. There is a linear decay of the fuel and the major species detected were toluene, benzene, p-tolualdehyde, p-ethyltoluene and carbon monoxide. Kinetics steps leading to these intermediates are given. Combustion property observations of isolated boron slurry droplets were extended to in-house boron/JP-10 slurries with and without surfactants. The experimental results revealed that stabilizing agents are responsible for the violent disruption of the primary slurry droplet and strongly support the previously proposed hypothesis of

UNCLASSIFIED REPORT

ABSTRACT: (U) The spatial and temporal characteristics of human visual localization are studied using psychophysical techniques. The primary tasks studied are frequency discrimination and distance judgments in the plane perpendicular to the observer's line of sight. It is found that these tasks cannot be performed directly on the basis of simple transformations of the retinal image, but depend on stimulus context and on judgment of stimulus depth. Experiments are designed to isolate the process underlying these distance and size judgments from more distal visual processes. One prominent finding is that the localization process is remarkably insensitive to those aspects of the stimulus that most affect contrast detection thresholds. Keywords: Human vision; Visual psychophysics; Visual spatial localization.

Chemical Communications, v21 p1605-1606 1987.

ABSTRACT: (U) The reactions of disilenes lead to many new classes of silicon compounds, including several three and four membered rings which present novel problems in chemical bonding. We report here the reaction of a disilene with an isonitrile to form the first disilacyclopropanimine. The addition of the colourless 2, 6-dimethylphenyliso-cyanide (57 mg) to a yellow solution of tetra(2,6-dimethyl-phenyl)disilene (200 mg) in 2 ml of benzene at room temperature, resulted in an immediate colour change to deep red. Upon standing, crystals (1) suitable for X-ray crystallographic analysis were obtained from this reaction mixture (Scheme 1). The compound decolorizes slowly, both in solution and in the solid state, on exposure to air. The reaction leading to (1) may be viewed as a (2 + 1) addition of the carbene-like carbon of the isonitrile to the disilene, and represents the first clear example of such a reaction. In contrast, similar reactivity is not observed for alkenes, but strained cyclic or electron rich alkynes are reported to react with isonitriles in benzene solution to form cyclopropanimines.

ABSTRACT: (U) A common assumption made in modeling system life from series and parallel systems is that the component lives are independent. This study investigates the magnitude of the errors one may incur by erroneously assuming the component lifetimes have independent exponential distributions when in fact the lifetimes follow the bivariate exponential distribution of Marshall & Olkin (series or parallel systems) or that of Freund (parallel systems). Keywords: Reprints; Mathematical models.

ABSTRACT: (U) The present paper employs potential well arguments to obtain a sharp existence-nonexistence alternative for solution to the linear heat equation subject to a nonlinear boundary condition.

ABSTRACT: (U) The use of sol-gel coatings to strengthen
oxide glasses has been demonstrated for the case of fused
silica. Increases in strength to as much as 2.2 times the
strength of uncoated glass have been obtained. The
strengthening does not involve the annealing of surface
microcracks, but rather the filling-in of such flaws. The
strengthening does not depend on coating thickness over
the range 2000-10 000 Å, but does depend significantly
upon the state of hydrolysis of the substrate surface.

ABSTRACT: (U) The Peterson reaction involves the
addition of an alpha silyl carbanion to the carbonyl
group of a ketone or aldehyde to yield a beta silyl
alkoxide, which decomposes to an alkene and a silanoate.
Similarly, the reaction of the sodium salt of
hexamethyldisilazene with nonenolizable ketones yields N-
(trimethylsilylimines). Bis(trimethylsilyl)carbodiimide
has been prepared by the reaction of sodium
bis(trimethylsilyl) amide with phosgene, while reaction
of lithium (trimethylsilyl) amides with sulfur dioxide
gives N-sulfinylamines. We now report that symmetrical
bis(arylsulfur diimides) can be prepared by reaction of
lithium (trimethylsilyl) anilides with thionyl chloride.

Automatic Control, VAC-32 n12 p1135-1139 Dec 87.

ABSTRACT: (U) The optimal projection equations for
reduced-order state estimation are generalized to allow
for singular (i.e., colored) measurement noise. The noisy
and noise-free measurements serve as inputs to dynamic
and static estimators, respectively. The optimal solution
is characterized by necessary conditions which involve a
pair of oblique projections corresponding to reduced
estimator order and singular measurement noise intensity.

SUPPLEMENTARY NOTE: Pub. in IEEE Transactions on
Automatic Control, VAC-32 n12 p1076-1084 Dec 87.

ABSTRACT: (U) Three parallel gaps in robust feedback
control theory are examined: sufficiency versus necessity,
deterministic versus stochastic uncertainty modeling, and
stability versus performance. Deterministic and
stochastic output-feedback control problems are
considered with both static and dynamic controllers. The
static and dynamic robust stabilization problems involve
deterministically modeled bounded but unknown measurable
time-varying parameter variations, while the static and
dynamic stochastic optimal control problems feature state
control-, and measurement-dependent white noise. General
sufficiency conditions for the deterministic problems are
obtained using Lyapunov's direct method, while necessary
conditions for the stochastic problems are derived as a
consequence of minimizing a quadratic performance
criterion. The sufficiency tests are then applied to the
necessary conditions to determine when solutions of the
stochastic optimization problems also solve the
deterministic robust stability problems. As an additional
application of the deterministic result, the modified
Riccati equation approach of Petersen and Hollot is
generalized in the static case and extended to dynamic
compensation.

SUPPLEMENTARY NOTE: Pub. in IEEE Transactions on
Automatic Control, VAC-32 n11 p1005-10.3 Nov 87.

ABSTRACT: (U) A new robust stability and performance
analysis technique is developed. The approach involves
replacing the state covariance by its block-norm matrix,
i.e., the nonnegative matrix whose elements are the norms
of subblocks of the covariance matrix partitioned
according to subsystems dynamics. A bound (i.e., majorant)
for the block norm matrix is given by the majorant
Lyapunov equation, a Lyapunov-type nonnegative matrix
equation. Existence, uniqueness, and computational
tractability of solutions to the majorant Lyapunov
equations are shown to be completely characterized in
terms of M matrices. Two examples are considered. For a
damped simple harmonic oscillator with uncertain but
constant natural frequency, the majorant Lyapunov
equation predicts unconditional stability. And, for a
pair of nominally uncoupled oscillators with uncertain
coupling, the majorant Lyapunov equation shows that the
range of nondestabilizing couplings is proportional to
the frequency separation between the oscillators, a
result not predictable from quadratic or vector Lyapunov
functions.

ABSTRACT: (U) The role of vibrational excitation of the umbrella bending mode of ND_3 and ammonia ion on the reaction with NH_3 and ND_3 is examined over the 2 to 12 eV center of mass kinetic energy range. Isotopic substitution permits the investigation of charge transfer, proton/deuteron transfer, and neutral atom abstraction. The charge transfer channel is moderately enhanced by excitation of the ammonia ion v2 vibrational mode. The proton/deuteron channel is suppressed by vibrational excitation of the ion at low kinetic energies. The hydrogen/deuterium atom abstraction channels show nearly a factor of 6 vibrational enhancement relative to NH_3 ion. The ion vibrational and translational energy play inequivalent roles in the reactions, indicating that nonstatistical factors are important in the transition from reactant to product channels. A simple dynamical model is offered to explain both the proton/deuteron transfer and the neutral atom abstraction reactions; it is based on the argument that vibrational motion along the particle transfer coordinate promotes reaction while vibrational motion perpendicular to the transfer coordinate hinders reaction.

ABSTRACT: (U) The effects of vibrational excitation of the ammonia inversion mode on the reaction of the ammonia ion with methane have been measured in a tandem quadrupole mass spectrometer over the center of mass collision energy range 1.5 to 10 eV. The hydrogen abstraction channel is enhanced by nearly a factor of 2 at nine quanta of vibrational energy relative to the $\nu = 0$ level of the ion. Added vibrational in the ammonia ion umbrella-bending mode facilitates the transition to the NH_4 product ion geometry. Protonated methylamine is formed at lower kinetic energies by attack of the ion at the methane carbon center, but with increasing vibrational excitation of the ammonia ion, the protonated methylamine decomposes by 1,2-elimination of molecular hydrogen and by C-N bond scission.

ABSTRACT: (U) First and second-order accurate the consistent versions of the coupled strongly implicit procedure (CSIP) have been developed and investigated for diffusion, potential flow and reduced Navier-Stokes (RNS) equations. Typical examples for the flow over an airfoil and a flat plate at incidence are presented. The method is also applicable to space marching for 3-D flows. Primitive variable forms of the (RNS) and the boundary region equations are considered for low speed flow near the trailing edge of a finite-span plate for supersonic flow over a cone at incidence, respectively. The composite velocity formulation is considered for flow over a cylinder of rectangular cross-section.

ABSTRACT: (U) The aim of this work during the last year has been to carry out research on new types of optical microscopes which gives better resolution in both the transverse and range directions than standard high-quality optical microscopes. The reason for carrying out such studies is that there is a need for measurements of semiconductor profiles with submicron resolution. The scanning electro microscope has excellent transverse resolution, but poor range resolution; it must be used in a vacuum, and it can damage sensitive semiconductor materials. We have been working with new scanning optical microscope concepts which provide excellent range resolution, of the order of 10nm, less, and transverse resolutions of the order of 200nm, and with computer processing as good as 130nm.

ABSTRACT: (U) Work is carried out on the dynamics of Ga and As scattering, sticking, and desorption from silicon single crystals using laser probing of the Ga and As (dimer) gas phase species. In the last six months, results have been obtained for the binding energy of Ga on silicon. Structural patterns of Ga on silicon at various coverages have been determined by LEED studies. Results have been obtained for the desorption of two different Ga spin-orbit states and a model developed to explain the observed behavior. The desorption pre-exponential factors suggest a one-dimensional mobility of Ga on silicon. These results are relevant to the epitaxial growth of GaAs on silicon. ABSTRACT: (U) The overall research program described in this report is to investigate the interaction of low (keV) and hyperthermal (10-100 eV) ions with clean and adsorbate-covered metal surfaces; in particular, ion-surface charge exchange processes. We report on the operation of the UHV scattering apparatus for the ion scattering measurements, ongoing development and upgrade of the apparatus, the use of two ion scattering simulations which together cover the entire energy range of interest, the further development of these simulations, and most importantly, the ongoing experiments to determine charge transfer probabilities. The data we present in this report are representative of the scattering spectra we measure. Completed analysis of these and similar spectra will be presented in forthcoming papers. To date, we have measured spectra for Li+, Na+, K+, He+, Ne+, and Ar+ beams, ranging in energy from 50 eV to 4 keV, scattered from the <001> and <1-10> azimuths of Cu(110). Important features of these spectra have been identified with the scattering simulations. Keywords: Hyperthermal ion beams, Resonant charge exchange, Scattering dynamics, Ion scattering instrumentation.

ABSTRACT: (U) Equations are derived to govern the motion of vehicles which move on rolling wheels. A relation between the centers of curvature of the trajectories of the wheels and the center of rotation of the vehicle is established. From this relation the general kinematic laws of motion are derived. Applications to questions of offtracking (the difference between the trajectories of the front and back wheels of the vehicle) and optimal steering (how to steer around a tight corner) are considered. Keywords: Euler-Savary formulae, Offtracking, Optimal steering.

UNCLASSIFIED REPORT

ABSTRACT: (U) In this work, a discrete time single server queueing system with arbitrary (finite) number of input streams, is considered. The input streams are assumed to be independent but successive arrivals in a single stream are not. More specifically, it is assumed that for each stream, arrivals are governed by an underlying finite state space Markov chain and that a visit to a state corresponds to one or more arrivals, according to a stationary mapping rule. The first in-first out service policy is adopted. For the system described above we develop a method to calculate the average number of customers in the queueing system. Then, the mean time that a customer spends in the system is calculated by using Little's theorem.

UNCLASSIFIED REPORT

ABSTRACT: (U) In this paper we derive a Poisson bracket on the phase space $so(3) \times so(3) \times so(3)$ such that the dynamics of two three dimensional rigid bodies coupled by a ball and socket joint can be written as a Hamiltonian system. This paper we introduce a Poisson bracket on the phase space. $SO(3)$ is the dual of the Lie algebra of $SO(3)$, so that the dynamics of two rigid bodies coupled by a ball and socket joint can be written as the Hamiltonian system $H = (F, H)$. This sets the stage so that the stability and asymptotics of the system can be studied using the energy Casimir method as in Holm, Marsden, Ratiu and Weinstein 1985 and Krishnaprasad 1985; so that chaotic solutions can be found using the Melnikov method such as in Holmes and Marsden 1983; so that bifurcations of the system can be described using the techniques in Golubitsky and Stewart 1986 and Lewis, Marsden and Ratiu 1986; and so that control issues can be studied, as in Sanchez de Alvarez 1986.

ABSTRACT: (U) In order to recognize 3-dimensional
objects in 2-dimensional scenes a shape description,
complete enough to determine the 3-dimensional object,
must be recovered from the scene. Although it is possible
to recover some 3-dimensional information, for instance
shape from shade (21) or shape from texture (13), in
general the information recovered will be a 2-dimensional
representation of the object. Many methods are available
for interpreting 3-dimensional objects in 2-dimensional
arrayed range images (3), 20; however this is considered
as a somewhat different problem, since depth information
can be derived from the scene with little or no ambiguity.

SUPPLEMENTARY NOTE: Pub. in Jnl. of Chemical Physics, v87 n7 p4147-4153, 1 Oct 87. See also Part 1, AD-A119 193.

ABSTRACT: (U) Theories of the mechanical, vibrational, and electronic properties of III-V semiconductors have been developed and applied to (i) help determine the feasibility of InN-based visible and ultraviolet lasers and light detectors, (ii) develop a theory of phonons in semiconductor alloys, (iii) elaborate on the physics of photoelasticity, (iv) understand surface reconstruction of semiconductors, and (v) predict the effects of atomic correlations on the light-scattering (Raman) properties of semiconductor alloys.

ABSTRACT: (U) Desorption of an adatom from a solid surface through vibrational excitation by an IR laser is studied using a generalized master equation approach and the isomeric approximation. A sharp transition from no desorption to almost instantaneous desorption is seen as the bound to continuum population transfer rate is varied. The critical rate increases linearly with laser power. Keywords: Reprints; Infrared lasers; Laser induced desorption; Vibrational excitation; Theoretical approach; Generalized master equation; Linear laser power dependence.

UNCLASSIFIED REPORT

SUPPLEMENTARY NOTE: Pub. in Physical Review B, v36 n9
p4664-4670, 15 Sep 87.

ABSTRACT: (U) The problem of the decay rates for molecules at rough metallic surfaces is considered, where the classical electromagnetic energy transfer theory of Chance, Prock and Silbey for a flat surface is generalized to the case of a rough boundary. A dynamical theory is constructed through the combination of the Sommerfeld antenna theory and the integral equation formalism of Maxwell's equation at rough boundaries established mainly by Maradudin, Mills and Agarwal. Perturbative solutions are obtained and numerical results are given with reference to a shallow sinusoidal grating surface. The results, when compared with those previously from the application of the image field theory, show that this latter theory can be very inaccurate for cases involving highly-conducting substrates or large molecule-surface distances, consistent with previous observations for the case of flat surfaces. Keywords: Energy transfer, Classical decay rates, Molecules, Rough metallic surfaces, Sommerfeld antenna theory, Maxwell's equations.

SUPPLEMENTARY NOTE: Pub. in Macromoles, v20 p1726-1727 1987.

ABSTRACT: (U) Polyphosphazenes comprise a broad class of macro-molecules with the general formula (NPR₂)_n. The physical properties of polyphosphazenes can be understood in terms of a highly flexible backbone, with specific physical or chemical characteristics imposed by the side groups. This side-group influence depends on the size, shape, polarity, and flexibility of the side units. In earlier work, we have explored the influence on the polymer properties exerted by flexible aliphatic side groups or rigid units such as phthalocyanine, TCNQ, steroidal, and other planar or rigid structures, both linked directly to the chain and separated from it by flexible spacer groups. One objective of these studies was to identify those molecular structural features that might lead to side-chain liquid crystalline behavior. A conclusion reached from these studies was that liquid crystalline behavior was probably accessible provided the appropriate mesogenic groups could be linked to the polyphosphazene chain through a sufficiently flexible spacer unit. Thus, our recent studies have focused on the synthesis of polymer 1, a species in which the mesogenic aromatic azo unit is linked to the polymer chain through tri(ethylene oxide) spacer groups.

ABSTRACT: (U) Investigations of both macroscopic and microscopic properties of thin film superconducting materials have been carried out. Compounds under study prior to the discovery of high-Tc superconductors, were either technologically significant, or involved possible unique mechanisms for superconductivity whose realization might extend the range of critical parameters. These include low carrier density superconductors, selected Heavy Fermion Compounds, and Chevrel Phase superconductors. Among the low-carrier density systems were films of Lead Tellurium and mixtures of Lanthanum Sulfide. These were prepared with the idea of ultimately fabricating FEI-like devices. Films of the Heavy Fermion Compounds UPt3 and UBe13 were prepared and the critical fields and proximity effects in the latter were studied. With the advent of the high-Tc materials the program shifted to their study and measurements of their time-dependent magnetization, XPS spectra, and tunneling spectra were carried out on both bulk and thin film materials.

ABSTRACT: (U) Our work has concentrated on developing a unifying framework, under the name UNITY, for studying problem solving in parallel programming independent of specific architectural considerations. We have proposed a simple model of computation and a logic to reason about properties of such programs and have managed to study problems from a variety of problem areas. We have developed a number of transformations which are appropriate for implementations on a variety of architectures: sequential, asynchronous shared memory, distributed message passing, synchronous parallel with shared memory, systolic arrays, and VLSI chips. The diversity of the application areas and the architectures studied lends credence to our hypothesis that there is a UNITY to computer programming.

ABSTRACT: (U) We should like to report the direct formation of 1-aryl-5-(N-aryl-N-benzoylamino)tetrazoles by the solid liquid phase-transfer catalyzed (PTC) reaction of diarylcarbodiimides, aryl chlorides, and sodium azide in toluene. With both sodium and potassium azide, in the absence of PTC catalyst the reaction gave recovered diarylcarbodiimides and aryl isocyanates. It should be noted that while there are numerous successful liquid-liquid PTC reactions, solid-liquid PTC reactions are still quite rare. Tetrabutylammonium chloride was used as the PTC catalyst. We believe that a sequence of reactions begin by migration of the ion pair to the surface of the solid sodium azide where anion exchange occurs resulting in formation of a toluene soluble tetrabutylammonium cation azide anion pair and precipitation of sodium chloride. Nucleophilic addition of azide anion to the central carbon of the carbodiimide 1 yields an amide anion which reacts with aryl chloride 2 to give an N-aryl-N-aryl-N-arylcabamimidic azide and simultaneously regenerates a ion pair.

SUPPLEMENTARY NOTE: Pub. in Jnl. of Electroanalytical Chemistry, v229 p1-17 1987.

ABSTRACT: (U) Studies by means of Auger spectroscopy, LEED and voltammetry are reported of the surface layers which were formed when a well-defined silver (111) surface was immersed into aqueous halide solutions (KF, KCl, KBr, KI) at controlled pH and electrode potential. Electrode potentials spanning the range from water reduction to silver oxidation were studied at pH 4 and 10. Surface composition (F, Cl, Br or I, O, K, and Ag) was monitored as a function of electrode potential by means of Auger spectroscopy following immersion. Strong adsorption of Cl, Br and I but not F occurred throughout most of the potential range, including simple immersion at open-circuit. Strength of adsorption of Cl and Br diminished significantly at extremely negative potentials near the solvent-reduction limit at pH 10; however, iodide was absorbed strongly at all potentials studied. Reductive desorption of Cl and Br from Ag (111) involved transfer of one electron per halogen atom in a very broad voltammetric peak spanning much of the accessible potential range.

ABSTRACT: (U) The multidimensional inverse scattering problem for an acoustic medium is considered within the homogeneous background Born approximation. A constant density acoustic medium is probed by a wide-band plane wave source, and the scattered field is observed along a receiver array located outside the medium. The inversion problem is formulated as a generalized tomographic problem. It is shown that the observed scattered field can be appropriately filtered so as to obtain generalized projections of the scattering potential. For a 2-D experimental geometry, these projections are weighted integrals of the scattering potential over regions of parabolic support, whereas they become surface integrals over circular paraboloids for the 2-D case. The inversion problem is therefore similar to that of x-ray tomography, except that instead of being given projections of the object to be reconstructed along straight lines, parabolic or paraboloid projections are given. The inversion procedure that we propose is similar to the x-ray solution, in the sense that it consists of a backprojection operation followed by 2- or 3-D space invariant filtering. An alternative interpretation of the backprojection operation in terms of a backpropagated field is given. A Projection-Slice Theorem is also derived relating the generalized projections and the scattering potential in the Fourier transform domain.

SUPPLEMENTARY NOTE: Pub. in Inorganic Chemistry, v24 p4449-4450 1985.

ABSTRACT: (U) This communication describes the first $Fe_2(CO)_6$ complex in which a carbonyl group bridges two phosphorus atoms. The chemistry of $Fe_2(CO)_6$ complexes includes derivatives in which a carbonyl group bridges two nitrogen atoms (e.g. $(RNCNR)Fe_2(CO)_6$, $R = C_6H_5$ and CH_3) or two sulfur atoms (e.g. $S_2COFe_2(CO)_6$). This communication describes the phosphorus atoms. Of particular interest is the apparent origin of this phosphorus-bridging carbonyl from a terminal carbonyl group bonded to iron. Such carbonyl migration from iron to phosphorus suggests that phosphido bridges might play an active role in metal carbonyl systems for the catalytic reduction of carbon monoxide.

ABSTRACT: (U) The (diisopropylamino)halophosphine metal carbonyl complexes $i\text{-Pr}_2\text{NP}(\text{H})\text{XM}(\text{CO})_5$ ($\text{X} = \text{Cl}, \text{Br}; \text{M} = \text{Cr}, \text{Mo}, \text{W}$) and $i\text{-Pr}_2\text{NP}(\text{H})\text{C}1\text{Mn}(\text{CO})_2\text{Cp}$ are readily by selective cleavage of one of the phosphorus nitrogen bonds in the corresponding hydrogen halide, HX. The phosphorus halogen bonds in these (diisopropylamino)halophosphine metal carbonyl complexes are potentially reactive toward nucleophiles including transition-metal nucleophiles that provide possible routes to bimetallic derivatives. This paper describes reactions of the above $i\text{-Pr}_2\text{NP}(\text{H})\text{X}$ metal carbonyl complexes with the highly nucleophilic metal carbonyl anion $\text{C}_5\text{H}_5\text{Fe}(\text{CO})_2^-$ to give novel heterobimetallic complexes that may be regarded as metal carbonyl derivatives of the trivalent phosphorus ligand $\text{CpFe}(\text{CO})_2\text{P}(\text{H})(\text{N}-i\text{-Pr}_2)$ in which the phosphorus atom is bonded to hydrogen, nitrogen, and iron. Such complexes do not have direct metal-metal bonds but undergo facile photochemical loss of one carbonyl group to give metal metal-bonded micro-phosphido derivatives according to the general scheme ($\text{X}=\text{H}, \text{Y}=\text{N}-i\text{-Pr}_2$).

DESCRIPTORS: (U) *HYDROGEN COMPOUNDS, *METAL CARBONYLS,

ABSTRACT: (U) The previous paper of this series
 discussed reactions of bis(diisopropylamino)phosphine,
 (i-Pr₂N)₂PH, with the mononuclear metal carbonyl
 derivatives (THF)M(CO)_n (n = 4, M = Fe; n = 5, M = Cr, Mo,
 W), (THF)₂Mn(CO)₂Cp, and fac-(EtCN)₃W-(CO)₃ to give the
 corresponding mononuclear (i-Pr₂N)₂PH metal carbonyl
 complexes. This paper describes reactions of (i-Pr₂N)₂PH
 with the metal metal bonded binuclear metal carbonyl
 derivatives Mn₂(CO)₁₀ and Co₂(CO)₈. Such reactions follow
 a different course, giving the binuclear
 bis(diisopropylamino)phosphido metal carbonyl hydride (i-
 Pr₂N)₂PMn₂(CO)₈H in the case of Mn₂(CO)₁₀ and the
 trinuclear diisopropylaminophosphinidene metal carbonyl
 complex i-Pr₂NPCo₃(CO)₈ in the case of Co₂(CO)₈. The
 structures of these two complexes have been determined by
 x ray diffraction.

ABSTRACT: (U) Bis(diisopropylamino) phosphine, (i-Pr₂N)₂PH, has recently become readily available through the
 LiAlH₄ reduction of (i-Pr₂N)₂PCl. Metal carbonyl complexes
 of (i-Pr₂N)₂PH are of interest because they contain
 potentially reactive phosphorus hydrogen and phosphorus
 nitrogen bonds. This paper describes a number of
 mononuclear (i-Pr₂N)₂PH metal carbonyl complexes as well
 as the cleavage of one or, in one case, both phosphorus
 nitrogen bonds in such complexes with hydrogen halides to
 give the corresponding metal carbonyl complexes of the
 ligands i-Pr₂NP(H)X(X=C1, Br) and Br₂PH.

ABSTRACT: (U) The objective of the current study was to
explore the reaction of nitroacetylenes and to synthesize
trinitroethyl and fluorodinitroethyl derivatives of
heteroaryl aromatics. Below we summarize the results of
these research areas: (1) Reactions of Nitroacetylenes.
We have successfully prepared the two new cycloadducts
from the reaction of a nitroacetylene with diazomethane
and trimethylsilylazide: 4-nitro-5-(trimethylsilyl)
triazole and 3-nitro-4-(trimethylsilyl) pyrazole. (2)
Synthesis of Polynitroheteroaromatic Explosives. We have
synthesized a new class of polynitroheteroaromatic
explosives designed to meet Air Force mission
requirements. These include N,N'-bis(trinitroethyl)-1,4-
diaminotetrazene, N,N'-bis(fluorodinitroethyl)-1,4-
diaminotetrazene as well as the fluorodinitro and
trinitroethyl esters of 2,3-pyrazine-dicarboxylic acid, 3-
4-pyridinedicarboxylic acid, and 3,5-pyridine
dicarboxylic acid. Keywords: Chemistry, Synthesis,
Polynitro compounds, Nitroacetylenes, Nitramines,
Nitroolefins.

ABSTRACT: (U) The cationic xanthene dyes thiopyronine and selenopyronine are solubilized in the Stern regions of anionic micelles. Upon photoexcitation, the excited triplet states of the dyes are observed to decay via unimolecular processes for the case of one dye per micelle and via bimolecular processes for the case of triplet states that undergo slow decay is measured, the number of micelles can be obtained and thus the micellar aggregation numbers can be evaluated. The aggregation numbers of several surfactant alkanesulfonates, 2,5-dialkylbenzenesulfonates with a total of 14 carbon atoms in the alkyl chains, and other detergents, which are determined in this manner, are in agreement with corresponding values determined by using other photophysical methods and with literature values. The aggregation numbers of the dialkylbenzenesulfonate surfactants increase from 38 to 56 with increasing effective chain length. The fluorescence lifetime and fluorescence depolarization of thiopyronine solubilized in the dialkylbenzenesulfonate micelles are consistent with a low local polarity and high local viscosity for the interior of these micelles, compared to micelles of

UNCLASSIFIED REPORT

ABSTRACT: (U) This work involves a continuing effort to provide a set of critically evaluated, internally consistent, high temperature thermochemical tables; the JANAF Thermochemical Tables. During this contract period, the chemical species studied fell into three categories - alkaline earth species, alkali metal species, alkali metal species, and elements. The species in the alkaline metal series include the metals themselves, hydroxides, halides, oxides, sulfides, sulfates and carbonates. The species in the alkali metal series include the halides and the carbonates. The elements under study include boron and aluminum. The support information gathered for the study of these chemical species has been collected together in a concise readable form and is available upon request. The calculation of the thermodynamic functions for diatomic gases was greatly enhanced by the addition of two calculational techniques. These procedures permit a more accurate accounting of the vibrational-rotational energy levels for each electronic state, including the metastable levels just above the dissociation limit. These procedures are particularly important in those cases where the electronic potential energy curve is very shallow, i.e. diatomic beryllium. Keywords: Enthalpy of formation, Entropy, Gibbs energy function, Gibbs enthalpy of formation, Heat capacity, Thermochemical tables, Enthalpy.

UNCLASSIFIED REPORT

ABSTRACT: (U) Turbulent multiphase flows (particle-laden jets, particle-laden flows in ducts, sprays, etc.) have technical applications for the combustion processes of airbreathing propulsion systems, and solid and liquid rocket motors. This report describes an upgrade of a single channel laser Doppler anemometer (LDA) to provide critical measurements needed to gain a better understanding of this class of multiphase flows. The upgrade yields a system which can be configured in several ways: a phase-discriminating LDA which provides either two phase-velocity components at a single point, or phase velocities at two points which are independently transversible; and a phase-Doppler LDA which can provide two-component particle (or drop) size and velocity information at a single point. All systems can yield particle (or drop) number fluxes. The arrangement of these systems is described along with some representative results using the phase-discrimination configuration. Keywords: Dilute dispersed flows; Laser Doppler anemometry; Multiphase flow; Particle-laden jet flow.

ABSTRACT: (U) The application of surface skimming bulk wave (SSBW) technology to sensors, and to an accelerometer in particular, was investigated through further studies of the properties of the SSBW mode, and through the design, fabrication, and evaluation of a laboratory SSBW cantilever beam accelerometer. The long-term stability of the SSBW mode for devices immersed in a damping fluid was shown to be equal to the stability of vacuum sealed devices (approx. 5 ppm/year). The relevant properties of the dual delay line configuration (SSBW devices on both sides of a single substrate) were investigated. The damping of mechanical vibrations in a cantilever quartz beam was studied, establishing the fact that critical damping of the beam can be achieved without difficulty. Evaluation of SSBW accelerometer models showed that the acceleration sensitivity of these devices can be accurately predicted from theory, and that fluid damping can reduce the vibration sensitivity of the SSBW oscillator to less than 5×10 to the minus 8th power/G. The results of this study indicate that a practical milli-G range SSBW accelerometer can be developed.

ABSTRACT: (U) For a given sparse symmetric positive definite matrix, a compact row-oriented storage scheme for its Cholesky factor is introduced. The scheme is based on the structure of an elimination tree defined for the given matrix. This new storage scheme has the distinct advantage of having the amount of overhead storage required for indexing always bounded by the number of nonzeros in the original matrix. The structural representation may be viewed as storing the minimal structure of the given matrix that will preserve the symbolic Cholesky factor. Experimental results on practical problems indicate that amount of savings in overhead storage can be substantial when compared with Sherman's compressed column storage scheme.

UNCLASSIFIED REPORT

ABSTRACT: (U) The goal of this program is to develop a concept for an optical computer architecture for symbolic computing by defining a computation model of a high level language, examining the possible devices for the ultimate construction of a processor, and by defining required optical operations. In the quarter we undertook a detailed evaluation of our optical architecture (SPARQ) for combinator graph reduction. Since we had determined that the interconnection network was the bottleneck in the performance of the architecture, our focus was on the message throughput of the simple register-based network. We derived an accurate performance model for the equivalent bidirectional ring network and found that the net parallelism in the architecture was indeed restricted by the low message traffic in the network. When messages exhibit no locality, the throughput for a 1024 processor network is 27. With local messages, the maximum throughput for the same network is 27. All results were subsequently verified by limited to 8 simulations.

ABSTRACT: (U) This report considers packet radio performance in mobile fading channels. The first chapter considers the optimal packet size for NPCSMA scheme in mobile fading channels. Here, modified expression for the channel throughput of nonpersistent carrier sense multiple access protocol (NPCSMA) in slow Nakagami fading channel is given. The optimal packet size and the acknowledgement size are obtained such that a maximum number of users can share the channel while maintaining reliable values for both the probability of packet and acknowledgement error. Meanwhile the useful throughput is also insured to be at maximum value. The second chapter considers packet radio performance over fast fading channels. Here, expressions for the throughput and packet delay of nonpersistent carrier sense multiple access (NPCSMA) protocol in fast fading environment are derived. Upper and lower bounds are obtained for a case where the fading phenomena is neither slow or fast. An alternative technique is used to approximately predict the performance for the cases that exist between these bounds. Both Nakagami fading and noncoherent reception are assumed.

ABSTRACT: (U) This paper introduces the class of two-point boundary-value descriptor systems (TPBVDS), discrete-time systems described by possibly linear dynamics and a set of boundary conditions constraining the values of the system state at the two endpoints of the system's interval of definition. By introducing a standard form for regular pencils we obtain a new and simple generalized Cayley-Hamilton theorem that simplifies our investigation of well-posedness, Green's function solution, and reachability and observability that one can define for TPBVDS, associated with processes that propagate inward from and outward toward the boundaries. We investigate each of these in detail, obtaining, among other things, far simpler forms for the reachability and observability results found previously in literature. In addition we describe several methods for the efficient solution of TPBVDS, one involving recursions from each end of the interval toward the other and two others involving recursions that proceed outward toward and inward from the boundaries.

SUPPLEMENTARY NOTE: Pub. in Bulletin of the American Meteorological Society, v68 n4 p321-328 Apr 87.

ABSTRACT: (U) During the late summer of 1985 a field experiment was conducted to investigate mountain top winds over a broad area of the Rocky Mountains extending from south central Wyoming through northern New Mexico. The principal purpose of this experiment was to further investigate an unexpectedly strong and potentially important wind cycle observed at mountaintop in north central Colorado during August 1984. These winds frequently exhibited nocturnal maxima of 20 to 30 m/s from southeasterly directions and often persisted for eight to ten hours. It appears that these winds originate as outflow from intense mesoscale convective systems that form daily over highland areas along the Continental Divide. However, details of the spatial extent and variability of these winds could not be determined from routine, regional weather data that are mostly collected in valleys. Although synoptic conditions during much of the 1985 experiment period did not favor diurnally recurring convection over the study area, sufficient data were obtained to verify the regional-scale organization of strong convective outflow at mountaintop elevations. In addition, the usefulness and feasibility of a mountain

UNCLASSIFIED REPORT

ABSTRACT: (U) This paper studies the dynamics of coupled planar rigid bodies, concentrating on the case of two or three bodies coupled with a hinge joint. The Hamiltonian structure is non-canonical and is obtained using the methods of reduction, starting from canonical brackets on the cotangent bundle of the configuration space in material representation. The dynamics on the reduced space for two bodies occurs on cylinders in IR(3); stability of the equilibria is studied using the Energy-Casimir method and is confirmed numerically. The phase space of the two bodies contains a homoclinic orbit which produces chaotic solutions when the system is perturbed by a third body. This and a study of periodic orbits are discussed in part II. The number and stability of equilibria and their bifurcations for three bodies as system parameters are varied are studied here; in particular, it is found that there are always 4 or 6 equilibria.

UNCLASSIFIED REPORT

ABSTRACT: (U) In recognizing a grasped object or grasp an object stably with a multifingered robotic hand, tactile sensors mounted on robot fingers have been identified as essential detecting tool. In general, grasp stability has two requirements: sliding avoidance and excess force avoidance. Hence, it is required that a tactile sensor be able to detect the nature of the force distribution which exists between the surface of the grasped object and the robot finger. Several kinds of tactile sensors have been designed based on electro-optics, piezoresistive, or piezoelectric properties, etc. Typically, these sensors are not used to measure the contact force directly, but to measure the interior strain or stress in an elastic finger pad. When sharp and rigid objects, e.g., a wedge indenter, indent an elastic material, very high stress is developed at the contact surface. This stress is reduced by distance from the contact area, so a fragile sensor would be better protected with a layer soft material. Another advantage of using an elastic covering is that the contact area becomes large so that grasp stability may be enhanced and the features of grasped objects better distinguished. The goal of this paper is to study how a surface force profile may be estimated from the information on strain or stress distribution detected by tactile sensors. This problem is referred to as the inverse problem since we can consider the stress or strain within an elastic material as the response due to surface loading.

ABSTRACT: (U) Results obtained for MBE grown N & P-type layers in terms of carrier concentration and electron or hole mobilities. Most layers grown after the start date of the current contract. It is important to point out that even if these results are the best ever obtained in the laboratory they are representative of our level of control concerning the growth. Numerous layers with the same composition exhibit very similar results. A new Hg cell, which is a prototype built by ISA - Riber is currently being tested in the laboratory. This cell that we have conceived gives a very stable Hg flux during hours of growth. It should be noted that both mobility and carrier concentration values are suitable for IR device application. UNCLASSIFIED REPORT

ABSTRACT: (U) This grant was for the purchase of equipment to establish a subcellular fractionation and patch clamping facility at Baylor College of Medicine. Experiments involve the isolation of an enriched fraction of mossy fiber synaptic terminals from adult rats. We have been investigating mechanisms of transmitter release, using biochemical and electrophysiological techniques. We have used the centrifuges successfully to develop this preparation of enriched mossy fiber synaptosomes. The computer, microscope, and isolation table are in use as a patch clamping facility to study the electrophysiological properties of these terminals. We have successfully measured the potassium stimulated and calcium dependent release of endogenous glutamate from these terminals. We have found that several phorbol esters are able to potentiate this release of glutamate, and we are in the process of investigating the mechanisms underlying this enhanced release. Our patch clamping has met with only limited success thus far. Although we have shown that the technique can be successfully applied to these small terminals, we have yet to make recordings of single calcium channels. The channels recorded thus far appear to be nonselective cation channels. We are currently in the process of altering our procedures and are hopeful that this aspect of the project will meet with more success in the very near future.

ABSTRACT: (U) Studies by LEED and Auger spectroscopy of Lead electrodeposited from aqueous Hydrochloric Acid solutions onto well-defined Platinum surfaces are reported. Adsorption of HCl from pure aqueous HCl solutions (PH=0 to 4) onto Pt(111) at electrode potentials from 0.4 to 0.8 volt (versus AgCl reference electrode) resulted in a stable (3x3) adlattice; however, below 0.4 volt adsorption was weak and desorption occurred readily under the influence of the electron beams employed for LEED or Auger spectroscopy. When Pb ions were present in the chloride solution, spontaneous (open circuit) electrodeposition of Pb occurred altering the sizes, shapes, and intensities of beams in the (3x3) pattern. Electrodeposition of Lead under conditions of negative linear potential scan resulted in a series of ten peaks at potentials more positive than the peak for deposition of bulk Pb. LEED patterns obtained after emersion of the surface at various stages during the scan revealed that the electrodeposited layer was ordered and underwent a series of structural transitions with increasing Pb coverage. Comparison of the Auger signal for Pb with the coulometric charge for Pb deposition demonstrated that the Pb deposit was not stable at open circuit (as in emersion). The Auger signal for Cl was not generally

ABSTRACT: (U) In regression analysis, the response is often transformed to remove heteroscedasticity and/or skewness. When a model already exists for the untransformed response, then it can be preserved by applying the same transform to both the model and the response. This methodology, which is called transform both sides, has been applied in several recent papers and appears highly useful in practice. When a parametric transformation family such as the power transformations is used, then the transformation can be estimated by maximum likelihood. The maximum likelihood estimator, however, is very sensitive to outliers. This article proposes diagnostics to indicate cases influential for the transformation or regression parameters. Also proposed is a robust bounded-influence estimator similar to the Krasker-Welsch regression estimator. Keywords: Reprints; Nonlinear models; Covariance matrix; Fisheries analysis.

ABSTRACT: (U) We consider the asymptotic nonlinear filtering problem $dx = f(x) dt + \text{sq. rt. } \epsilon \text{ } dW$, $dy = h(x) dt + \text{sq. rt. } \epsilon \text{ } dV$, and obtain the limit as $\epsilon \rightarrow 0$. The power of the filter approaches 0 of $\epsilon \log \log(1/\epsilon)$ to the epsilon power. $W(x, t)$ is the value function for a deterministic optimal control problem arising in Mortensen's deterministic estimation, and is the unique viscosity solution of a Hamilton-Jacobi-Bellman equation. Hjab has also studied this filtering problem, and we extend his large deviation result for certain unnormalised conditional measures. The resulting variational problem corresponds to the above control problem.

ABSTRACT: (U) Local feedback stabilization of bifurcated solution branches is studied. Two cases are considered: that in which the nominal system undergoes a Hopf bifurcation as a parameter is varied, and the case of a stationary bifurcation from a simple zero eigenvalue. For each case, results on the existence of a stabilizing feedback are given. Moreover, simple synthesis techniques for the stabilizing controllers are discussed. A concept of proximity stabilization is introduced as an alternative to stabilization in the ordinary sense for systems that are not locally stabilizable. A result is stated on the genericity of proximity stabilizability. Motivation for further research in several areas is given. Keywords: Control systems; Electrical engineering.

ABSTRACT: (U) Progress to date is summarized as follows:
1. Experimental confirmation has been made of the pulse formation mechanism in a laser modelocked by a slow saturable absorber as proposed by New and Haus. 2. We have shown analytically and experimentally that the degree of coherence is the same in a diode laser whether modelocked or singlemode at the same power. 3. The continuously operating phosphate Nd:glass laser has been modelocked for the first time ever to generate 7 ps pulses. We have also successfully amplified these pulses to J/pulse at 500 Hz rate. Keywords: Neodymium lasers; Pulsed lasers; Photoconductivity; Optoelectronic devices; Nitrogen laser; Low energy lasers.

UNCLASSIFIED REPORT

ABSTRACT: (U) As the MBE growth technique has continued to improve for Hg(1-x)Cd(x)Te films, the prospects for films of larger area have begun to be explored. These larger area films are important for imaging arrays and will be especially vital in the future for the efficient production of Hg(1-x)Cd(x)Te material. The growth of MBE of uniform Hg(1-x)Cd(x)Te epilayer on a large substrate is very difficult to achieve because of the non-uniform distribution of the fluxes and on the non-uniform temperature of the substrate. Keywords: Molecular Beam Epitaxial(MBE); Mercury; Cadmium; Tellurium.

DESCRIPTORS: (U) *ELECTRONIC EQUIPMENT, *MERCURY, *MOLECULAR BEAMS, *MERCURY COMPOUNDS, *CADMIUM TELLURIDES, ARRAYS, CADMIUM, DISTRIBUTION, EFFICIENCY, FILMS, IMAGES, NONUNIFORM, PROCESSING, PRODUCTION, SUBSTRATES, TELLURIUM, TEMPERATURE.

UNCLASSIFIED REPORT

ABSTRACT: (U) This final report form the Department of Statistics, University of Georgia, concerns the above referenced grant, an equipment grant that provided partial funding for the acquisition of specified computing equipment to support research in the department. The report is in three parts headed Equipment Acquired, Research Supported, and Department Progress. In discussion of the equipment acquired, summaries of purchases made and proposed intended purchases are provided. These summaries are supplemented by comments on equipment changes and a few notes on difficulties encountered. Summaries of computer equipment use are provided under research supported; subsections deal with research described in the proposal, other departmental research, and future research benefits. Finally, changes have occurred in the department and these are noted in a final section. Keywords: Block designs; Parameter estimates; Reliability models; Nonparametric Functions estimates; Statistical inference; Stochastic processes.

ABSTRACT: (U) A simple linear calibration function can be used over a wide concentration range for the inductively coupled plasma (ICP) spectrometer due to its linear response. The random errors over wide concentration ranges are not constant, and constant variance regression should not be used to estimate the calibration function. Weighted regression techniques are appropriate if the proper weights can be obtained. Use of the calibration curve to estimate the concentration of one or more unknown samples is straightforward, but confidence interval estimation for multiple use of the calibration curve is less obvious. We describe a method for modeling the error along the ICP calibration curve fit. Multiple and single-use confidence curve are compared.

ABSTRACT: (U) Drawing upon a combination of the experimental, theoretical and computational methods to investigate the cause and mechanism of the Eckert-Weise effect. Acoustic resonance established experimentally that the vortex street is indeed the cause. Through the theoretical and computational investigations, the dynamical mechanism for the instantaneous $T_{sub t}$ separation around vortices, which is the root of the effect but hidden in the time-average, is considered. The mechanism comprises three key ingredients: (i) the low-pressure fields at the vortex centres, (ii) their convective movement, and (iii) the entrainment of fluid particles by vortices into the wake and their ejection out of it. The unsteady change in $T_{sub t}$ as encountered by a fluid particle along its path may duly be regarded as a natural compressor-turbine process (for an interesting interpretation of the $T_{sub t}$ change in turbomachines viewed solely from the unsteady equation. For a low subsonic Mach number, $P_{sub t}$ is predicted to become separated in a manner similar to $T_{sub t}$. Thus the well-known defect of the time-averaged $P_{sub t}$ behind a bluff body may be re-interpreted as the super position of unsteadily separated structures. The instantaneous $T_{sub t}$ and $P_{sub t}$ separation, not limited to the vortex street, should be present even in such three-dimensional vortical flows as the large-scale structure along the periphery of jets.

SUPPLEMENTARY NOTE: Pub. in Inorganic Chemistry, v26 n13 p2106-2109 1987.

ABSTRACT: (U) Complexes containing bonds between silicon and a group 12 metal have been known for many years. Recently, the isolation of thermally unstable zinc and cadmium derivatives completed the family of binary silyls $\text{M}(\text{SiMe}_3)_2$ ($\text{M} = \text{Zn}, \text{Cd}, \text{Hg}$). Apart from $\text{Hg}(\text{SiMe}_3)_2$, which has been shown to be a useful silylating reagent, the reactivity of zinc, cadmium, and mercury silyl derivatives has not been extensively investigated. Our studies of transition-metal-silicon chemistry have prompted us to search for new silylating agents. In particular, we have sought new methods for introducing the sterically hindered $-\text{Si}(\text{SiMe}_3)_3$ ligand into the coordination sphere of high-valent, coordinatively unsaturated metal complexes. The lithium silyl $(\text{THF})_3\text{LiSi}(\text{SiMe}_3)_3$ can be used to silylate some metal halides, but in many cases decomposition resulting from reduction of the metal center is observed.

UNCLASSIFIED REPORT

ABSTRACT: (U) Innovative techniques for obtaining particle size and velocity are being investigated. The four methods are: phase Doppler, ratiometric light scatter detection, Lagrangian frame particle analyzer, and scattered light heterodyne interferometry. Although these methods have overlapping capabilities, each offers additional possibilities for providing heretofore unavailable data. The phase Doppler method has been highly refined and provides reliable particle size and velocity measurements. However, research has been required on the light scattering mechanisms due to nonuniform-light scattering theory and experimental observations have required the expansion of the theory to include the effects of nonuniform illumination. Under certain conditions, the detection of refracted light where none is predicted, remains as a question to be resolved. These questions apply to all of the methods addressed. However, the ratiometric techniques may be used in the on-axis forward scatter light detection mode. This will allow the measurement of irregular-shaped particles moving at high speed using light configuration. The system is limited to dilute particle fields. Currently, the theoretical analysis and optical configuration have been completed and preliminary tests have shown that the basic concept will work. Interests in turbulent dispersion of spray drops suggested the need

ABSTRACT: (U) This report summarizes research conducted by S-Cubed to develop advance constitutive models of plain and reinforced concrete for ultimate use in the cost-effective design and hardness assessment of concrete protective structures. The specific goals of the research are: (1) development of a mixture theory which can accurately account for steel-concrete interaction and (2) formulation of an advanced constitutive theory for plain concrete which can accurately portray its nonlinear, inelastic behavior including damage and microcracking for arbitrary loading histories. The importance of the steel-concrete interaction and the nonlinear inelastic behavior of the plain concrete, including cracking, is emphasized. Keywords: Concrete failure modes; Continuous damage model; Dwell action; Evolution equation; Endochronic theory.

UNCLASSIFIED REPORT

ABSTRACT: (U) The principal objective of this study was to perform basic research investigations into an innovative power conversion concept for trans atmospheric, beamed energy propulsion: a new class of External Surface Impulse (ESI) thrusters. This advanced thruster principle could be used for atmospheric VTOL, high acceleration, and lateral flight (e.g., short-term cruise) propulsion of Single-Stage-To-Orbit (SSTO) beam-powered shuttlecraft of the next century. Three classes of ESI thrusters were initially examined: 1) simple thermal, 2) electrostatic and 3) electromagnetic. Beam power wavelengths from 10cm (microwave) to 0.3um (laser) were considered. The subsequent research effort concentrated on the simple thermal repetitively-pulsed ESI thrusters, energized with laser power and using air as the working fluid. Laser frequencies were selected because of the relative wealth of experimental data and theoretical research on laser impulse coupling which exists in the literature. The first year analytical effort has proven conclusively that such an engine can deliver high levels of thrust-to-beam-power at liftoff (e.g., at least an order-of-magnitude greater than beam-powered hydrogen-fueled rockets), with infinite specific impulse (decreased only, perhaps, by

UNCLASSIFIED REPORT

ABSTRACT: (U) An experimental investigation of the three dimensional laminar boundary layer separation associated with an incident swept shock wave was conducted in the von Karman Institute (VKI) S-1 supersonic wind tunnel operating at Mach 2.15. Mean velocity profiles were measured both in the attached separated and reattachment flow regions using a laser doppler velocimeter. A comparison of the measurements with a full 3D Navier-Stokes solver, developed at the VKI, exhibited good agreement in all three regions, thus validating the code which was based on the Beam-Warming algorithm. The report also reviews the earlier parts of the grant dealing with the necessary developments in LDV to achieve high quality data, and the of the 2D shock boundary layer interaction. Keywords: Two dimensional flow; Three dimensional flow; Laminar boundary layer; Flow separation.

ABSTRACT: (U) A continuous-flow, horizontal gradient,
ice thermal diffusion chamber has been developed and
tested for heterogeneous ice nucleation of aerosol
particles under accurately controlled supersaturations
and supercooling in the absence of a substrate. The
chamber consists of preprocessing, main and crystal
settling sections. In the preprocessing and main sections,
top and bottom plates are coated with clear, smooth ice
by a new method. The main section maintains a range of
supersaturations across the sample flow. Sample air is
sandwiched with filtered and predried air to avoid wall
effects and transient supersaturations. Nucleated
crystals are received on Mylar copy film in the settling
section and processed for analysis based on their
temperatures and supersaturations at nucleation. Two
numerical models are developed and used to evaluate
transient supersaturation development in the shear flow
and wall effects in the vertical plane across the flow.
Stability of sample flow is confirmed with smoke tests.

UNCLASSIFIED REPORT

ABSTRACT: (U) This project was to determine the extent to which metabolism of trichloroethylene (TCE) to trichloroacetic acid (TCA) was responsible for its hepatotoxic and hepatocarcinogenic effects in rodents. Ethanol was used as a more or less selective means of decreasing the production of TCA. This information was useful in determining whether these effects are relevant to human exposures to these chemicals. During the first year of this project, it was established that dichloroacetic acid (DCA), trichloroacetic acid and chloral hydrate (CH) all are capable of inducing single strand breaks in hepatic DNA of both mice and rats in vivo at much lower doses than could TCE. Metabolism studies suggest that the production of TCA can be modified by ethanol coadministration. Experiments revealed that DCA produces a cytomegalia that is seen uniformly throughout the liver of the mouse. This effect is characterized by massive accumulations of glycogen. It does not produce this effect in rats given even higher doses, nor is the effect duplicated completely by TCA. In addition, mice treated with DCA are displaying focal areas of change that appear preneoplastic after only 24 weeks of treatment with DCA. These results suggest that DCA may play a more important role in the hepatotoxic and hepatocarcinogenic effects of TCE than had been previously appreciated. Keywords: Trichloroethylene, Hepatotoxicity, Ethanol, Hepatocarcinogenicity.

ABSTRACT: (U) Since October 1983, a new coherent backscatter radar has been in operation at Goose Bay, Labrador, for the purpose of studying small-scale electron density structure in the high-latitude ionosphere. This radar operates over a frequency band that extends from 8 to 20 MHz, and it uses an electronically phased array of 16 log-periodic antennas for both transmission and reception. The radar transmits a seven-pulse pattern that enables one to determine 17-lag complex autocorrelation functions of the backscattered signals as a function of range and azimuth. In this paper we present a complete description of the radar including explanations of the operation of the phasing matrix, the techniques of data acquisition and analysis as implemented in the radar microcomputer, and the possible on-line and automatic operating modes that may be instituted. We also present examples of some of the initial results that we have obtained with the radar during the afternoon and late evening hours. These examples include images of the two-dimensional distribution of small-scale structure and of their associated mean Doppler motion. We also present examples of F region Doppler spectra derived from the complex

ABSTRACT: (U) This paper introduces general row merging schemes for the QR decomposition of sparse matrices by Givens rotations. They can be viewed as a generalization of row rotations (or merging). Based on the column ordering and the structure of the given sparse matrix, we present an algorithm to determine automatically a sequence of submatrix rotations appropriate for sparse decomposition. It is shown that the actual numerical computation can be organized as a sequence of reductions of two upper trapezoidal full submatrices into another upper trapezoidal full matrix. Experimental results are provided to compare the practical performance of the proposed method and the specific scheme. Significant reduction in arithmetic operations and factorization time is achieved in exchange of a very modest increase in working storage. The interpretation of general row merging as a special variable row pivoting method is also presented.

DESCRIPTORS: (U) *DECOMPOSITION, *SPARSE MATRIX, ALGORITHMS, ARITHMETIC, COMPUTATIONS, NUMERICAL METHODS AND PROCEDURES, REPRINTS, ROTATION, STORAGE, TIME, VARIABLES, ORTHOGONALITY, EXPERIMENTAL DATA.

ABSTRACT: (U) The design and performance of several dispersive spectrometers for reflection absorption infrared spectroscopy are presented. Sources of noise and their control are discussed in detail. Individual component selection for the spectrometers is discussed with particular attention paid to optimizing sensitivity for surface measurements. These efforts culminated in an ellipsometric spectrometer with a sensitivity of <0.01% absorption and capable of following transients with a temporal resolution of 10 ms. Keywords: Infrared spectroscopy, Ellipsometry, Surface species, Surface reactions.

ABSTRACT: (U) Two dimensional laser induced fluorescence imaging offers prospects for non invasive, spatially and temporally resolved measurements of species concentrations and mole fractions, temperature, density, velocity and pressure in gaseous flowfields. Here we report two recent examples of research to develop such diagnostic capability: simultaneous imaging of OH and hydrocarbon (C2H2) distributions in premixed ethylene air flames; and temperature imaging in heated air using single photon fluorescence of oxygen. Keywords: Acetylene, Oxygen, Combustion, Temperature.

p293-304 1985.

ABSTRACT: (U) Electrochemically formed homo-polyazulene and mixed polyazulene-polypyrrole films have been studied by infrared spectroscopy. Infrared spectra are consistent with a polymerization mechanism that involves loss of hydrogen atoms and produces an amorphous polymer structure. The spectral differences between the oxidized (conducting) and reduced (non-conducting) forms of polyazulene show the presence of a polarization interaction in the oxidized polymer, even though the structure of both forms is similar. The i.r. bands of anions are present only for the oxidized form of the polymer, a result that indicates the existence of the cationic charge centres on the polymer backbone. The counter anions have no detectable effect on the polymer structure and only a small effect on certain vibrational bands of the oxidized form. The electrochemical preparation of a mixed polyazulene polypyrrole phase is discussed and the mixed phase is found by i.r. spectroscopy to be a random copolymer. A bilayer polymer structure consisting of polyazulene and polypyrrole was also prepared and the i.r. spectra of this polymer structure did not indicate any interfacial interactions.

ABSTRACT: (U) This work describes the advancements in the field of acoustic microscopy in superfluid helium at temperatures near 0.1 K. The microscope is presently capable of imaging materials using 300 A sound waves with 200 A resolution. Current developments include the search for operation of higher frequencies in order to get better resolution and improvements in the signal-to-noise ratio to get better images. A new technique has been developed to fabricate high efficiency acoustic transducers at ultra high frequencies. These transducers consist of multilayers of zinc oxide with alternating crystal structure. Multilayer transducers fabricated with the new technique have shown to convert nearly 10% of the electrical input power to acoustic power at frequencies as high as 30 GHz. This is several orders of magnitude better than any of the previous experiments. Keywords: Acoustic microscopy; Superfluid helium, Sound waves; Super; Acoustic transducers.

ABSTRACT: (U) The review on a new type of para-catenated
aromatic polymer being used in the preparation of high-
performance films and fibers of exceptional strength,
thermal stability, and environmental resistance,
including inertness to essentially all common solvents.
Polymers of this type include the cis- and trans-poly(p-
phenylene benzobisoxazole) (P80), the cis- and trans-
forms of the corresponding poly-(p-phenylene
benzobisthiazole) (PBT), and the structurally similar
poly(5,5'-bibenzoxazole-2,2'-diyl-1,3-phenylene) (AAPB0)
and poly(2,5-benzoxazole) (ABP80) and their sulfur-
containing analogues. Because of their rigidity, these
polymers become highly oriented in solution and some
display liquid crystalline behavior. The purpose of this
paper is to summarize the authors' theoretical work on
the structures, conformational energies and
intermolecular interactions for these chains, including,
in some cases, the so-called articulated forms and the
protonated forms known to exist in strong acids. The
emphasis is on how such studies provide a molecular
understanding of the unusual properties and processing
characteristics of this new class of materials.

ABSTRACT: (U) Recent studies suggest that the hairpin vortex plays an important, possibly dominant, role in the dynamics of turbulent flows near walls. This study addresses the following topics of the motion of hairpin vortices near solid walls on a theoretical basis: the nature of the evolution of hairpin vortices in a shear flow; the type of flow induced near a wall by a convected hairpin vortex; the character of the viscous response near a wall to the hairpin vortex motion; and the nature of the interaction of 2 hairpin vortices. A numerical procedure is developed to allow accurate evaluation of the trajectory of a 3-dimensional vortex for vortices having small cores. The integration method is based on a numerical approximation to the Biot-Savart integral; most existing vortex calculation methods have severe stability problems for vortices with small cores. These problems are overcome with the present method and technique is applied to compute the evolution of convected vortex loops and hairpin vortices, both in uniform flow and in shear flow above a wall. For hairpin vortices evolving in a shear flow, a regenerative process is observed wherein secondary hairpin vortices form outboard of the original hairpin vortex in a manner consistent with experimental

ABSTRACT: (U) Experiments were carried out to assess Mach number effects on boundary layer due to generic fin and swept compression corner geometries. An extensive set of fin interaction experiments was carried out at constant Reynolds number over the Mach number range of 2.5 to 4.0. Data thus far consist of surface flow visualization photographs and laser light-screen visualizations of flowfield structure. Additional experiments were conducted to assess the possibility that experimental data of this type might depend on the wind tunnel facility in which the experiments were performed. That was not found to be the case. Results of the parametric Mach number study revealed that Mach number effects over the range considered are essentially inviscid. These were accounted for simply by referencing measured quantities to the freestream Mach angle. The interaction growth with increasing shock strength was found to be nonlinear, contrary to previous results. Initial results from swept compression corner experiments are also reported. Keywords: High speed flows; Viscous inviscid interactions; Supersonic flow; Flow visualization; Fluid dynamics; Flow separation.

ABSTRACT: (U) This Annual Report details a program of research on composite spinel ceramic materials with enormous specific heat maxima in the temperature range 5-20 K. The results obtained so far have suggested an attractive picture for the ordering phenomena in the B-site spinels, CdCr204 and ZnCr204. Significant progress in characterizing and controlling the fabrication of the spinel materials has been made. Pure powders, compacted disks, as well as the 9/1 columbite composite have been made and characterized. Magnetocaloric experiments reveal no trace of hysteresis, which means that the phenomena involved in the low temperature transitions in the Zn and Cd spinels must involve second order transitions. Adiabatic demagnetization cooling above TN and also at low temperatures is indicative of paramagnetic spins, while a region of demagnetization heating just below TN seems to indicate anti-ferromagnetic ordering. Measurements have also discovered an amazing anomaly in the dielectric constant at the anti ferromagnetic transition. Keywords: Ceramic, Magnetocaloric, Spinel.

ABSTRACT: (U) The Center for Nonlinear Dynamics of the Brain (CNDB) studies nonlinear dynamics of large masses of nerve cells in animal and human brains as the basis for explaining the self-organization of goal-directed cognitive behaviors. We believe that this approach to the study of mass neural action will be a basic method of the neurophysiology of the twenty-first century. Our research has application to clinical neurology and psychiatry, to the measurement and enhancement of human mental capabilities and to the design of self-organizing, pattern recognition computer systems. By extending techniques and models derived from the paleocortex to animal and human neocortex, deeper understanding of the neural basis of goal-directed higher brain functions will emerge. The practical consequences of this enhanced knowledge will be better diagnosis of neurologic and psychiatric diseases. It also will result in the ability to predict decrements in higher brain functions consequent to illness, fatigue or drugs. The new models for globally parallel, self-organizing systems which result from this research also will be directly relevant to the design of VLSI architectures for pattern recognition. Keywords: Mathematical modeling; Anatomical modeling.

EVJ50D

ABSTRACT: (U) This document considers the problem of control of a beam which is moving in the x-y plane. It extends from $x=0$ to $x=L$. The left end at $x=0$ is clamped to an actuator which moves the beam along the y-axis. The control input is the force $u(t)$ in y direction. While moving, the beam may vibrate. Let $z(t)$ denote the displacement of the left from $y=0$, and $w(t,x)$, the displacement of the beam from the line $y=z(t)$ at position x and time t . Suppose a position sensor is placed on the beam and the sensing output is $v(t)$, sub $O=z(t) + w(t,x_0)$, where $0 < x_0 < L$ is the sensor location. We are interested in the case when the flexure $w(t,x)$ of the beam is significant. The problem is to synthesize a feedback control law which moves the beam from one position to another in a stable manner. It is well known that when the sensor and the actuator are collocated a simple lead compensator suffices to produce a stable design. This result holds even when the beam dynamics are considered as a system with infinite zero-damping modes, and can be shown using root locus argument. This stabilization method may break down, however, when there is a positional gap between the sensor and actuator. In this case the classical compensation techniques are no longer effective. Time-domain optimization approaches based on state-space models have been applied to this problem. This article presents a case study of noncollocated beam control problem using frequency-domain optimization method proposed by Professor Kvakernaak. We emphasize the choice of the weighting functions in the cost function, and the search method which always leads to stable designs.

SUPPLEMENTARY NOTE: Pub. in Jnl. of Polymer Science:
Polymer Physics Edition, v23 p2193-2201 1985.

ABSTRACT: (U) Solid-state polymerization of furil, induced by reaction with AsF5 at the solid-gas interface, has been investigated by means of vibrational analysis of the reactant and the product. Infrared spectra are consistent with the mode of polymerization which involves an alpha linkage and subsequent loss of hydrogen atoms. The C/H elemental analysis suggests that the polymer consists of around six or seven monomeric units. The reaction product is found to be unstable at high temperatures; a prolonged annealing at this temperature leads to a different structure, possibly, by the opening of the furan rings. The x-ray powder diffraction study shows that the polymeric furil is crystalline, with a lattice similar to that of the monomer, but contains a considerable amount of disorder.

UNCLASSIFIED REPORT

ABSTRACT: (U) This volume provides a complete description of the structure and the operation of the specific controller software developed for ASU's digital Czochralski Growth Control System (CGCS) for compound semiconductors. The manual is primarily intended for use by advanced programmers and crystal growth specialists. In four main chapters, the Controller Software Reference Manual discusses the design considerations applied to digital LEC crystal growth control, give a short overview over the growth controller computer hardware and operating system environment, describes the functions of the CGCS from an operator's point of view, and delineates the internal operations of the controller software by discussing the controller software and algorithms. Various appendices provide tables of controller software tasks, routines, and variables, file format information, and lists of system messages and error codes. Keywords: Gallium arsenides.

DESCRIPTORS: (U) *ALGORITHMS, *COMPUTER PROGRAMS, *CRYSTAL GROWTH, *GALLIUM ARSENIDES, CONTROL, CZOCHRALSKI CRYSTALS, DIGITAL SYSTEMS, ERROR CORRECTION CODES, GROWTH(GENERAL), INTERNAL, MANUAL OPERATION, PROGRAMMERS, SEMICONDUCTORS, TABLES(DATA).

PAGE 199 EVJ500

ABSTRACT: (U) It is our belief that a thorough
understanding of the mathematical underpinnings of
elasticity is crucial to its analytical and numerical
implementation. For example, in the analysis of rotating
structures, if one attempts to couple geometrically
inexact models, obtained by linearization or other
approximations to rotating rigid bodies, one can easily
get serious artificial softening effects that can
significantly alter numerical results; see Simo and Vu-
Quoc for a discussion (compare equations of that paper).
In this paper, we consider geometrically exact models,
such as the Kirchhoff-Love-Reissner-Antman model for rods
and its counterpart for plates and shells. These models
take into account shear and torsion as well as the usual
bending effects in traditional rod and plate models. Our
purpose is to systematically develop the Hamiltonian
structure for the dynamics of these models in the
convective representation. The convective representation
is chosen for its computational convenience and for our
planned coupling of these models to the dynamics of rigid
body motion, as in Krishnaprasad and Marsden. One of the
topics that is of importance in the foundations of
elasticity is a geometric formulation of the equations in
Hamiltonian form.

UNCLASSIFIED REPORT

ABSTRACT: (U) High power lasers based in space have been considered as sources for power transmission, laser propulsion, materials processing and space defense. The feasibility of such systems is based on the cost per unit power delivered, with detailed studies indicating that light weight has a greater impact on cost than laser efficiency. Solar radiation is a natural source of power for these devices and two methods for conversion of solar radiation to laser radiation can be considered. An indirectly solar pumped laser would first convert the solar radiation to electricity or longer wavelength blackbody radiation which is then used to power the laser. A directly longer wavelength blackbody radiation which is then used to power the laser. A directly pumped solar laser would utilize a portion of the solar spectrum to directly pump the laser medium, eliminating the intervening step and substantially reducing the systems weight and complexity. Detailed comparisons showed a directly pumped laser with an overall efficiency of only 1.5 percent can compete with an indirectly energized solar laser with an overall efficiency of ten percent. With this in mind, a concept for a directly solar pumped laser was developed based on an alkali vapor (sodium) as the laser medium. Keywords: Solar, Laser.

ABSTRACT: (U) The first Workshop of Interface Phenomena concentrated on just three topics related to the kinetics of interface reactions: (1) adsorption-desorption kinetics, (2) precursors, (3) kinetics and phase transitions. The adsorption and desorption processes themselves are to be understood as surface bond making and breaking mechanisms, respectively. If the energy transfer is fast enough, then these processes can be understood in terms of thermodynamic arguments such as formulated in transition state theory. However, in most situations such as simple treatment is not sufficient and the details of the microscopic dynamics must be invoked. Unfortunately, this point is very frequently overlooked in the analysis of kinetic data of gas-surface reactions, leading to rather murky discussions in the literature. The phenomenological analysis of surface reactions in terms of kinetic rate equations quite often has to invoke precursor states as reaction intermediates to fit experimental data. However, because such an analysis rarely leads to a unique answer, independent evidence must be brought forward if precursors in a given reaction

are to be accepted as more than just mythical mis-fits. The equilibrium properties of surface phase transitions have been studied for many decades, and they exhibit a wealth of fascinating detail. The exploration of their kinetics, on the other hand, had to await the advent of time resolved surface analysis techniques. In particular, video-LEED has made it possible to study kinetics of surface reconstruction.

ABSTRACT: (U) Visible chemiluminescence in the spectral range 200-900 nm has been measured for the reactions of F atoms with a range of inorganic iodides studied at reduced pressures (ca. 0.7 mbar). There is only one emitter present in all cases viz. IF* (B). The IF* (B) vibrational state distributions and rotational temperatures are essentially the same for all the systems studied. The yield of IF* can be substantially increased by adding O2 (delta) to the flame or by increasing the F atom concentration. It is suggested that the origin of IF* (B) in these reactions and other similar systems previously studied may be the recombination reaction of spin-orbit excited iodine atoms with ground-state fluorine atoms. Keywords: Iodine monofluoride.

ABSTRACT: (U) This article deals with the problem of factoring a large sparse positive definite matrix on a multiprocessor system. The processors are assumed to have substantial local memory but no globally shared memory. They communicate among themselves and with a host processor through message passing. Our primary interest is in designing an algorithm which exploits parallelism rather than in exploiting features of the underlying topology of the hardware. However, part of our study is aimed at determining, for certain sparse matrix problems, whether hardware based on the binary hypercube topology adequately supports the communication requirements for such problems. Numerical results from experiments running on a multiprocessor simulator are included.

ABSTRACT: (U) Poisson processes play an important role in many fields. The Poisson process is one of the simplest counting processes and is a building block for many other processes, especially for general independent increment processes. Many definitions have been given for a counting process to be a Poisson process and many papers have appeared dealing with characterizations for the Poisson distribution and the Poisson process. Among the qualitative conditions defining a Poisson process, independent increments is one of the most important conditions. In this paper we attempt to use other conditions in place of independent increments. This provides a somewhat different viewpoint for examining Poisson processes. In addition, new characterizations for the nonhomogeneous Poisson process via moment conditions are obtained which might be easier to utilize in practice.

ABSTRACT: (U) A new graph model is presented to study the row annihilation and row ordering problems in the QR decomposition of sparse matrices using Givens rotations. The graph-theoretic results obtained can be used to derive good row orderings for certain column orderings, such as width-1 and width-2 nested dissection orderings. This model is different from the bipartite-graph model introduced in a previous work. We refer to the new model as implicit because the rows are not represented explicitly by nodes. In contrast to the bipartite-graph model, where the rows are represented by nodes in a bipartite graph.

ABSTRACT: (U) This research is focussed on the role of molecular switches in brain which regulate synaptic reactivity. We have identified a 47,000 mol wt phosphoprotein and its kinase (c) which play a pivotal role in this regulation. We have enhanced communication among nerve cells studied electrophysiologically by activation of this kinase. In the proposed research we specifically manipulate this brain phosphoprotein with novel kinase activating agents. In a new initiative, both the kinase and the F1 substrate will be studied with the goal of enhancing synaptic reactivity by regulating the activity of proteins that play a pivotal role in this process. Keywords: Nerve transmission; Synapse; Plasticity; Reactivity; Phosphorylation; Protein kinase C; Protein F1; Fatty acids.

SUPPLEMENTARY NOTE: Pub. in Large Scale Effects of
Seasonal Snow Cover, p315-327 Aug 87.

ABSTRACT: (U) The seasonal progression of snow melt on the Arctic ice pack was mapped from shortwave satellite imagery for 1977, 1979, 1984 and 1985. The four years showed substantial differences in the timing of the melt interval. The progression of melt in May and June of the earliest melt year (1977) was about three weeks ahead of the latest year (1979). As a result, basin-wide surface albedo varied by upwards of 0.08 in June, ranging from 0.58 in 1977 to 0.66 in 1979. May and July showed interannual variations in albedo of up to 0.05. The extent of snow melt varied from year to year in the central Arctic. The region was essentially snow-free by mid-July in 1977 and 1979, but retained some snow throughout the summer in 1984 and for all but two weeks in 1985. Although limited in extent, our data base suggests relationships between snow melt and Arctic surface air temperatures in spring, spring cloudiness, and the extent of late summer ice. (Reprints)

PROJECT NO. 2304

ABSTRACT: (U) In this paper we shall consider the question of uniform stabilization of thin, elastic plates through the action of forces and moments on the edge of the plate (or on a part of the edge of the plate). Two particular plate models will be considered: The classical fourth order Kirchhoff model, but incorporating rotational inertia, and the sixth order Mindlin-Timoshenko model. The difference in the two models, from a physical point of view, is that the M-T model incorporates transverse shear effects while the Kirchhoff model does not. Actually, the M-T model is a hyperbolic system three coupled second order partial differential equations in two dependent variables. The unknowns, denoted by w , ψ , ϕ are the vertical component w of displacement and angles which are measures of the amount of transverse shear. The three equations are coupled through terms which are multiples of a factor K called the coefficient of elasticity in shear.

ABSTRACT: (U) This program covers the growth and assessment of gallium arsenide and related compounds and alloys for use in microwave, millimeter wave, and optical devices. It also covers the processing of the material into devices, the testing of the devices, and the theoretical modeling of carrier transport in these devices. Both molecular beam epitaxy (MBE) and organometallic vapor phase epitaxy (OMVPE) are used for growth. The following specific tasks are pursued: Develop an improved understanding of the role of the substrate and growth parameters on the quality of device structures on GaAs and related materials grown by OMVPE. Investigate the frequency and power limits of power FET devices employing a two-dimensional electron gas in the channel. Investigate and improve heterojunction structures for transistor applications. Produce semiconductor light emitters capable of high speed amplitude modulation. Femtosecond optical investigation of hot carrier dynamics in III-V compounds and quantum wells. Develop high speed receivers for optical communication using optical field effect transistors and large area epitaxial photoconductive detectors. Use optical excitation to study carrier dynamics in compound semiconductors. Develop advanced design techniques for microwave GaAs FET amplifiers. Improve direct method of broad band circuit design, and Explore transient carrier transport in small III-V devices in boundary limited domain.

SUPPLEMENTARY NOTE: Pub. in Material Research Society Symposium Proceedings, v75 p539-550 1987.

ABSTRACT: (U) We have used molecular beam methods and temperature programmed desorption to probe the reaction of several hydrocarbons with the Si(100) surface at cryogenic temperatures. It has been found that the kinetics of the surface reaction with the C-C bond can be strongly influenced by the production of active surface sites using prebombardment with Ar ions. The chemistry of the adsorbate is also influenced by electron bombardment of the adsorbed layer. Conversely, capping of active sites with atomic hydrogen retards the kinetics of the surface reactions. Keywords: Silicon, Silicon carbide, Chemisorption, Active site, Propylene.

ABSTRACT: (U) This document considers stabilization
(minimum time to the zero solution) of wave and beam
equations via endpoint velocity control. In general it
considers a control system described by a partial
differential equation, with dependent variable denoted
 $w=w(t,x)$, which admits $V=$ the partial derivative with
respect to t as a symmetry generator and hence a
conservation law which implies conservation of energy.

ABSTRACT: (U) These proceedings are those of a symposium
held on 25 September 1986 at the National Academy of
Sciences, Washington, D.C., to commemorate and celebrate
the establishment, in 1946, of the U.S. Joint Services
Electronics Program (JSEP). In that year, forward-looking
scientists and administration leaders at universities
that had been engaged in wartime-related research, and
military service agencies of the federal government,
established JSEP for the purpose of carrying on
university-type research of interest to all components of
the military. The first of the universities involved were
the Massachusetts Institute of Technology, Columbia
University, Harvard University, and Polytechnic Institute
of Brooklyn. These were soon followed by Stanford
University, the University of California, Berkeley, the
Universities of Illinois, Southern California, Texas and
others. There are presently 12 universities in the
program, which has expanded and contracted from time to
time as interest and available funds have changed.

p669-676 1987.

ABSTRACT: (U) Coherent forward scattering atomic
spectrometry (CFS) consists of the rotation of linearly
polarized light as it passes through an atomic vapor
located within a transverse or a longitudinal magnetic
field, the Voigt effect or the Faraday effect,
respectively. A fuel rich air acetylene flame was used as
the atom reservoir in this study. A Glan-Foucault calcite
prism polarizer placed prior to the flame, was oriented
at a 45 angle to the magnetic field. A second polarizer,
the analyzer, is placed after the flame to detect the
amount of light which is rotated. When the analyzer is
oriented orthogonally to the first polarizer, the signal
produced is proportional to the square of the
concentration of the analyte. The CFS signal can be
linearized with the respect to concentration of
offsetting the analyzer by a small offset angle. A
comparison to the noise characteristics for the squared
and the linear systems was made in this study. The
results of the study provide valuable information in the
design, evaluation and optimization of a CFS spectrometer.
Keywords: Noise; Furnace; Coherent forward scatter;
Voigt effect; Flame; Multielement analysis.

ABSTRACT: (U) Two techniques are introduced to reduce
the working storage requirement for the recent
multifrontal method of Duff and Reid used in the sparse
out-of-core factorization of symmetric matrices. For a
given core size, the reduction in working storage allows
some large problems to be solved without having to use
auxiliary storage for the working arrays. Even if the
working arrays exceed the core size, it will reduce the
amount of input-output traffic necessary to manipulate
the working vectors. Experimental results are provided to
demonstrate significant storage reduction on practical
problems using the proposed techniques. Keywords:
Reprints; Cholesky factorization; Sparse matrix.

UNCLASSIFIED REPORT

ABSTRACT: (U) Four major goals were accomplished in the second year. Two related to synapsin I regulation of transmitter release and two related to the temperature dependence of the synaptic release process with a preliminary study of quantal release at the squid giant synapse. The results may be summarized as follows: (1) Demonstration that the dephosphorylated tail fragments of synapsin I do not regulate synaptic release which excludes the possibility that tail fragments themselves can prevent vesicular release. (2) Injection of head phospho synapsin I does not regulate synaptic release, demonstrating that the molecule itself does not interfere with vesicular fusion. These two experiments indicate that synapsin I works by affixing the synaptic vesicles to the cytoskeletal system. (3) Video-enhanced microscopy results demonstrated that axoplasmic mobility is not altered by either tail fragments or head phospho synapsin I, confirming the findings obtained by the electrophysiological study. The results demonstrate the mechanism by which synapsin I regulates transmitter release. A study of the temperature dependence of transmitter release demonstrated that temperature can be used to study the kinetics of synapsin I inhibition of transmitter release. Measurements of miniature potentials were finally accomplished routinely and can now be utilized as a technique to determine directly the effect

ABSTRACT: (U) During the past several years, a program of high-frequency radiowave studies of the high latitude ionosphere has been developed. Studies are now being conducted on the formation and motion of high-latitude ionospheric electron density irregularities, using a sophisticated high-frequency radar system installed at Goose Bay, Labrador. The radar antenna is also being used to receive signals from a beacon transmitter located at Thule, Greenland. This information is providing a better understanding of the spatial and temporal variability of high-latitude propagation channels and their relationship to disturbances in the magnetosphere ionosphere system.

ABSTRACT: (U) The overall goal of this research is to provide insights into the adaptive capabilities of individual neurons, which will lead to the development of machines having some of the information processing capabilities of the nervous system. During the period between 01 August 1984 and 31 July 1987, significant progress has been in three major directions. First, experimental studies on the modulation of ionic conductance mechanisms have been performed on individual neurons that are believed to contribute to neuronal plasticity and classical conditioning of defensive reflexes. Second, we have begun to identify elements of the neuronal circuit that contributes to operant conditioning of feeding behavior. Third, a single cell neuronal model for classical conditioning has been developed and simulated on a digital computer. Keywords: Learning, Memory, Information storage, Artificial intelligence.

ABSTRACT: (U) This effort involved research investigating improved iterative methods for solving sparse systems of linear equations. Research papers appearing in print during this period included such titles as On the minimum module of normalized polynomials. Extended numerical computations on the 1/9 conjecture in rational approximation Theory, and A study of semi-iterative methods for nonsymmetric systems of linear equations. A major accomplishment during this period of effort was the use of summability methods and conformal mapping techniques in the study of iterative methods, thus enhancing the theoretical foundations of such methods.

SUPPLEMENTARY NOTE: Pub. in Parallel Computing, v3 n4 p327-342 Oct 86.

ABSTRACT: (U) In this paper, a systematic and unified treatment of computational task models for parallel sparse Cholesky factorization is presented. They are classified as fine-, medium-, and large-grained graph models. In particular, a new medium-grained model based on column-oriented tasks is introduced, and it is shown to correspond structurally to the filled graph of the given sparse matrix. The task scheduling problem for the various task graphs is also discussed. A practical algorithm to schedule the column tasks of the medium-grained model for multiple processors is described. It is based on a heuristic critical path scheduling method. This will give an overall scheme for parallel sparse Cholesky factorization, appropriate for parallel machines with shared-memory architecture like the Denelcor HEP.

SUPPLEMENTARY NOTE: Pub. in Parallel Computing 5, p65-74 1987.

ABSTRACT: (U) A row oriented implementation of Gaussian elimination with partial pivoting on a local-memory multiprocessor is described. In the absence of pivoting, the initial data loading of the node processors leads to a balanced computation. However, if interchanges occur, the computational loads on the processors may become unbalanced, leading to inefficiency. A simple load-balancing scheme is described which is inexpensive and which maintains computational balance in the presence of pivoting. Using some reasonable assumptions about the probability of pivoting occurring, an analysis of the communication costs of the algorithm is developed, along with an analysis of the computation performed in each node processor. This model is then used to derive the expected speedup of the algorithm. Finally, experiments using Intel hypercube are presented in order to demonstrate the extent to which the analytical model predicts the performance.

Symposium, p15-25 Aug 87.

ABSTRACT: (U) A recursive-least-squares (RLS) adaptive fast transversal filter (FTF) for processing of continuous-time signals is presented. It has the same structure as the discrete-time-least-squares FTF, namely, a tapped-delay-line with time-varying gains, which are updated by propagating a set of coupled recursions. However, while the discrete-time scheme involves a fundamental unit of time (i.e., the sampling period of the signal), which determines both the duration of the delay and the rate of gain updating, our continuous-time scheme involves a delay of arbitrary duration and continuously-varying gains. Also, the conceptual and computational complexity of the continuous-time FTF is reduced in comparison to the discrete-time FTF.

ABSTRACT: (U) We study the stability condition of an M/G/1 priority queue with two classes of jobs. Class 1 jobs have preemptive priority over class 2 jobs. We consider three different types of preemptions and the effects of possible work loss (due to preemption) on the stability condition for the queueing system. Keywords: Priority queue, Preemptive scheduling. Stability condition, Reprints.

ABSTRACT: (U) The authors define for certain family distributions the maximum likelihood function L at a sample point x . It is shown that for the multivariate hypergeometric and multinomial families, the maximum likelihood function is a Schur convex function of x . In the language of majorization, this implies that the more diverse the elements or components of x are, the larger is the function $L(x)$. Several applications of this result are given in the areas of parameter estimation and combinatorics. An improvement and generalization of a classical inequality of Khintchine is also derived as a consequence.

ABSTRACT: (U) Diagnostics of nitrogen molecules in the
inductively coupled argon plasma (ICP) have been
evaluated with respect to collisional processes with
electrons, argon atoms, and nitrogen molecules. Based on
reaction probabilities, defined as the product of the
rate coefficient and number density of colliding species,
argon collisions were proposed as the dominant excitation
mechanism for rotational transitions of N, while
vibrational transitions showed complex behaviour
depending upon the vibrational quantum number.
Furthermore, the excitation mechanism for electronic
levels was considered by applying the collisional-
radiative model including heavy particle collisions, such
as mutual N impact and Penning processes. Keywords:
Nitrogen, Vibrational excitation, Rotational excitation,
Electronic excitation, Penning ionization, Electron
impact, Temperature.

ABSTRACT: (U) Continuous-time Markov chains are commonly used in system reliability modeling. This reprint discusses a method for automatically deriving transient solutions that are symbolic in t for acyclic Markov chains. Our method also includes parametric sensitivity analysis of the transient solution and several cumulative measures associated with Markov chain behavior. We include three examples, one to show the use of our method in evaluating approximate solution techniques, one showing parametric sensitivity analysis of a large Markov model, and one demonstrating the computation of cumulative measures for an acyclic Markov reward process. Keywords: Accumulated reward; Acyclic Markov chain; Markov chain; Markov reward process; Mean time to failure; Performability analysis; Reliability modeling; Sensitivity analysis; Transient analysis.

UNCLASSIFIED REPORT

ABSTRACT: (U) The objective of this research program was to design and develop direct band gap solar cells which would have high below band gap energy (infra-red (IR)) reflectivity for use in high efficiency thermophotovoltaic (TPV) energy conversion systems. Two types of customized GaAs cells were grown on intrinsic or semi-insulating GaAs substrates with either p-type GaAs or Al(.9) Ga (.1) As stop-etch layers. Holes were drilled through the substrate using a laser photochemical etch technique. Cells with high IR reflectivity and low series resistance were fabricated by drilling a hole which stopped at the contact layer of the cell with the Al(.9) Ga(.1) As stop-etch layer and then depositing gold in the hole and on the back surface. Measurements of these customized cells indicate that IR reflectivities in excess of 90%, corresponding to TPV efficiencies in excess of 35%, are feasible. Keywords include: Thermophotovoltaic energy conversion; GaAs solar cells; Photochemical etching; GaAs; Free carrier absorption; and Infra-Red reflectivity.

ABSTRACT: (U) Multiple-processor systems can provide higher performance and higher reliability/availability than single processor systems. In order to properly assess the effectiveness of multiprocessor systems, measures that combine performance and reliability are needed. We describe the behaviour of the multiprocessor system as a continuous time Markov chain and associate a reward rate (performance measure) with each state. We evaluate the distribution of performance for analytical models of two multi-processor systems using a recently developed polynomial-time algorithm that obtains the distribution of performance for non-repairable as well as repairable systems with heterogeneous components. The systems that we analyze are the (C.mmp) multiprocessor system developed at Carnegie Mellon University and a shared storage system proposed by researchers at the IBM Watson Research Center. These examples indicate that distributions of cumulative performance measures over finite intervals reveal behavior of multi-processor systems not indicated by the steady-state-values alone.

SUPPLEMENTARY NOTE: Pub. in Annals of Glaciology, v9 p1-6 1987.

ABSTRACT: (U) The seasonal progression of snow melt on Arctic pack ice is mapped from satellite shortwave imagery (0.4-1.1 micrometers) for four spring/summer seasons (1977, 1979, 1984 and 1985). This provides the first detailed information on the temporal change of the ice surface albedo in summer and of its year-to-year variability. Average surface albedo of the Arctic Basin for the years investigated falls from between 0.75 and 0.80 in early May to between 0.35 and 0.45 in late July and early August. In the central Arctic, where ice concentration remains high and 0.50 to 0.60. Overall, melt progresses poleward from the Kara and Barents Seas and from the southern Beaufort and Chukchi Seas, with the melt fronts meeting on the American side of the Pole. There are substantial year-to-year differences in timing, duration and extent of the melt interval. Progression of melt in May and June of the earliest melt year (1977) was about 3 weeks ahead of the latest year (1979). By late July, the central Arctic was essentially snow free in 1977 to 1979, but more than 50% snow covered in 1984.

ABSTRACT: (U) The working hypothesis has been that
longterm synaptic potentiation may mediate certain of the
mnemonic functions of the hippocampal circuitry. The
discovery of an underlying Hebbian conjunctive mechanism
has boosted confidence in this hypothesis. One major
effort of the past year was to summarize and integrate
this AFOSR supported discovery into a more general
theoretical and experimental framework. In regard to the
4 specific aims, development of the fluctuation algorithm
has been completed, and it was applied to synaptic
fluctuations obtained using the loose patch clamp method
(aim 2). The algorithm is currently running on a
mainframe at UCLA. It is now being implemented on a small
workstation (Macintosh II). As soon as it is working on
the Mac II, the quantal analysis in hippocampus will
begin (aim 1). The culture method is underway (aim 3) and
a first-generation video microscopic technique was
developed for visualizing neurons and their synapses to
see if the latter move during activity (aim 4).

ABSTRACT: (U) Laser cladding techniques have recently enjoyed attention in preparing in-situ novel surface clad alloys with extended solid solution. Mass transport involved in this process is rather intriguing since it plays the major role in producing new materials without being restricted by equilibrium phase diagram. Although earlier work has identified convection as the dominant factor for homogenous liquid metal composition, very little is understood about the solute redistribution at the solid-liquid interface under such nonequilibrium conditions. In this paper a mathematical model is presented for determining the composition of extended solid solutions formed due to rapid cooling in laser cladding. This model considers a diffusion mechanism for mass transport in a one-dimensional semi-finite solid substrate. The rate of solidification was obtained by modeling the cooling process as a composite medium heat transfer problem, and the discontinuity of the concentration field was simulated using nonequilibrium partition coefficient. A nonsimilar exact solution for the mass transport equation was obtained using a set of similarity variables derived using Lie group theory.

ABSTRACT: (U) 1) The biophysical mechanisms underlying long term potentiation (LTP) were investigated in indentifiable and monosynaptic excitatory inputs to hippocampal neurons. The results provide the first insights into the conductance changes that are responsible for the expression of LTP. 2) Both current-voltage-clamp measurements of the mossy fiber synaptic response in pyramidal neurons of region CA3 were made with a single-electrode-clamp system. The excitatory postsynaptic response was pharmacologically isolated by bathing hippocampal slices in saline containing picrotoxin, which blocks the synaptic inhibition that normally accompanies the experimentally evoked mossy fiber response. LTP was induced by tetanically stimulating the mossy fiber input of 1 s at 100 Hz. Before and 20 min to 1 h after inducing LTP, we attempted to measure the mean excitatory postsynaptic potential (EPSP) amplitude intrasomatic current-voltage relationship to a step current waveform, membrane time constant spike threshold peak excitatory postsynaptic current amplitude synaptic conductance increase and synaptic reversal potential but adequate assessments of all eight of these were not always obtained for every cell that was studied.

ABSTRACT: (U) This study was to investigate the potential for short wavelength generation through Raman up conversion in ultraviolet transmitting fibers. The study resulted in three key achievements: 1. Identification of induced absorption in fused silica UV fibers due to color center formation with the excimer laser at 193 nm. Optical bleaching to reverse the induced absorption was observed by using a longer wavelength of the excimer laser (XeF at 351 nm). A maximum recovery of 70% of initial transmission was obtained. This is the first time that color center formation and subsequent bleaching has been reported in UV transmitting fibers. 2. Development of new means to image single pulses from the excimer laser, utilizing a phosphor to down convert the image to video recorder. 3. Study of Raman up conversions using excimer lasers. Comparison was made of fibers vs. Raman resonators. Limited coherence length because of the bandwidth spread of excimer lasers and unavailability of low-mode-number UV fibers are reasons why the Raman resonator appears to be a reasonable approach.

ABSTRACT: (U) This final report summarizes the objectives and accomplishments of research on sublaminar damage mechanisms in composite structures. It may be separated into three elements. The first is interlaminar fracture analysis methodology development. Existing methods for predicting strain energy release rate components have been assessed, and two new alternative approaches have been developed and illustrated. The second is the creation of a phenomenologically based criterion for damage tolerance analysis of composite structures. An equivalent damage parameter and a relevant compliance measure are determined from experiments. This methodology has been validated by seven independent experiments. Keywords: Delamination, Damage tolerance, Damage in composites, Composite materials.

ABSTRACT: (U) The SUN system was ordered in September 1986. After long delays in production, the system was partially delivered in January-February 1987. The system was installed within two weeks and became functional in April-May 1987. Due to reduced amount of funds granted (\$150,000) a supplementary fund was obtained from the National Science Foundation (\$30,000) and Clarkson University has contributed \$20,000 as well. With these combined funds the system was made functional, after an ethernet installation. Several achievements can already be reported by the use of the SUN system despite its short service time.

UNCLASSIFIED REPORT

ABSTRACT: (U) Proposed was the purchase of a Molecular Beam Epitaxy (MBE) system as the key instrument to establish a coherent, interdisciplinary research program in the area of quantum well structure research. The system will have two growth chambers instead of the proposed single chamber. One is a conventional solid source MBE system and the other is the novel gas source MBE with organometallic sources. Our growth capability is thus enhanced by the acquisition of a system in which pioneering materials research can be performed. Custom modifications to the growth systems have been incorporated to allow non-standard, in situ MBE analytical studies to be performed. It is believed that our MBE system is at present unique in a US university. These programs will concentrate on basic material growth kinetics in gas source MBE, heterojunction and multi-quantum well (MQW) electronic and optical properties and devices for integrated optoelectronics.

SUPPLEMENTARY NOTE: Pub. in Information Processing
Letters, v23 p103-106 1986.

ABSTRACT: (U) The satisfiability problem (SAT) is the
problem of determining whether a given collection I of
disjunctions (clauses) of boolean literals can all be
satisfied (have value true) by some consistent assignment
of truth values to the literals of I (truth assignment).
SAT is NP-complete so there is no known efficient
algorithm for solving this problem. The Davis-Putnam
procedure (DPP)(4) is a well-known, much studied method
for solving instances of SAT. The probabilistic analysis
of variants of DPP under the assumption of constant-
density input distributions such as in (7,8,9) has given
the impression that the David-Putnam procedure is
intrinsically a very fast method for solving most
instances of SAT. This impression is moderated somewhat
by the results of this letter which show that the
following two trivial algorithms, run concurrently, solve
'more' instances of SAT in polynomial time than all
previously studies algorithms.

ABSTRACT: (U) A stochastic control problem with finite
fuel constraint is solved explicitly. It is shown to be
reducible to simpler stochastic optimization problems,
such as optimal stopping and singular control for
Brownian motion with unlimited fuel.

ABSTRACT: (U) The purpose of this paper is to extend
previous results in order to achieve more versatile,
convenient stability criteria for a wide class of finite-
difference approximations to initial-boundary value
problems associated with the hyperbolic system $u_{sub t} =$
 $Au_{sub x} + bu + f$ in the quarter plane $x > 0, t > 0$. With
these criteria, stability is easily established for a
large number of examples, where many of the cases studied
in the recent literature are included and generalized.

UNCLASSIFIED REPORT

ABSTRACT: (U) The recent accomplishments are reviewed for a research program employing combined analytical-experiments techniques to study the three dimensional characteristics and behavior of vortex motions associated with the turbulence production process in turbulent boundary layers. Progress is described in the development of a new image processing technique which allows the derivation of quantitative data from flow visualization images. The method is used to search for the role of hairpin vortices in the turbulence production process. In the analytical portion of the study, calculations have been carried out to compute the evolution of a pair of vortex in a shear flow; the interaction of a pair of hairpins has been examined as well as the viscous response at a wall due to the motion of a hairpin vortex. Comparison of these computer simulations with the experimental studies is very encouraging. Computations for the evolving flow between wall layer streaks during a typical cycle in the wall layer of a turbulent boundary layer have also been carried out; these studies show two possible routes to breakdown of the wall layer flow leading to the production process. Keywords: Turbulent boundary layers; Hairpin vortices; Vortex motion.

ABSTRACT: (U) Certain hyperbolic systems of partial differential equations which are known to be uniformly asymptotically stabilizable using point sensors/actuators (S/A) are considered. The issue to be investigated is the effect on stability when point S/A's are replaced by concentrated S/A's, that is, S/A's which average over small regions of the spatial domain. Although it is known that passing from point to concentrated S/A's necessarily destroys uniform stability, a necessary and sufficient condition for strong stability is obtained in terms of the S/A weighting functions. In addition, in the special case of a cantilevered beam controlled by a single sensor/actuator pair concentrated at the free end, another, more robust type of stability is shown to hold, even when strong stability does not. The latter result shows that the system energy is bounded by a part which goes uniformly to zero at infinity and a residual which can be explicitly estimated in terms of the support of the weight functions and the initial energy. Furthermore, the residual energy converges to zero as the support reduces to the point at the point at the free end of the beam.

ABSTRACT: (U) When two pulsed dye lasers are tuned in spatial and temporal coincidence to two connected atomic transitions in a flame or plasma, the resonance fluorescence monitored from the first excited level decreases due to the depletion of the population of that level induced by the second laser excitation step. The monitoring of such a decrease (fluorescence dip) can be shown from simple theoretical considerations to be useful for diagnostic studies and for the evaluation of some fundamental parameters of the atomic transition involved in the second excitation step. Both steady state and transient behaviour are discussed. The information content of the fluorescence dip is similar to that of the saturated fluorescence signal. However, several distinct advantages are offered by the new technique especially when the level reached by the second excitation step is close to the ionization limit of the atom. Keywords: Fluorescence, Laser excitation, Flame, Fluorescence dip, Plasma, Diagnostics.

ABSTRACT: (U) Correlations between either scalar or
vector quantities measured in the study of
photodissociation dynamics can serve to provide a very
detailed picture of the dissociative event. This article
discusses the use of Doppler profile and time of flight
spectroscopy to learn about the correlation between the
separate internal energies of two recoiling fragments, to
study the way in which the internal energy distribution
of a fragment varies with its recoil direction and to
determine the angle between a photofragment's recoil
velocity direction and its rotation vector. Two new
techniques are introduced. High-voltage switching of the
potential applied to a time-of-flight mass spectrometer
is used to map the velocity distribution of
photofragments onto their arrival time distribution.
Probing of photofragments by polarized light with sub-
Doppler resolution is used to determine the degree of
angular correlation between their rotation vector and
their recoil velocity vector. (Reprints)

ABSTRACT: (U) This report describes work addressing the problems of collisional induced oscillator strength and energy transfer from metastable states in Group IIA alkaline earth metal atoms. The quenching of CA 3PJ states when perturbed by rare gas atom collisions is investigated and such quenching is found to be negligible. The CA 1D2 state, however shows considerable collisional induced effects. Calculations have been performed which show that collision cross-sections for transfer of electronic excitation may be switched from the low values typically associated with off-resonant processes to the high values associated with resonant processes by using a strong laser to bring dressed states in one atom in and out of resonance with bare states in another atom. Keywords: Slow atomic collisions; Chemical lasers.

ABSTRACT: (U) A canonical form is derived for all linear
solvable systems $E(t)x'(t)+F(t)=f(t)$ with sufficiently
smooth coefficients E, F . Using this form it is shown
that for all smooth enough solvable systems a class of
recently defined numerical imbedding methods and an
algorithm to compute the manifold of consistent initial
conditions always work. In addition, necessary and
sufficient conditions are given on $E(t), F(t)$ to insure
solvability in the case when $E(t), F(t)$ are infinitely
differentiable. Keywords: linear time varying system;

ABSTRACT: (U) We consider a stochastic dynamic system
which is governed by a multidimensional diffusion process
with constant drift and diffusion coefficients. The
correction corresponds to an additive input which is
under control. There is no limit on the rate of input
into the system. The objective is to minimize the
expected cumulative cost associated with the position of
the system and the amount of control exerted. It is
proved that Hamilton-Jacobi-Bellman's equation of the
problem has a solution, which corresponds to the optimal
cost of the problem. An existence of optimal policy is
proved.

ABSTRACT: (U) A sequence of qualitatively robust
predictive source encoders, for a Gaussian stationary
source with outlier contaminated observation data, is
proposed and analyzed. Performance measures include mean
difference-sequence distortion and output entropy at the
nominal Gaussian source, as well as breakdown point and
influence function. The proposed sequence of predictive
encoders attains strictly positive breakdown point and
uniformly bounded influence function, at the expense of
increased mean difference-squared distortion and
differential entropy, at the Gaussian nominal source.

SUPPLEMENTARY NOTE. Pub. in Theory of Reliability, p143-
164 1985.

ABSTRACT: (U) Our objective is to develop methodology
for analyzing life test data. Initially, there is only
data-no mathematical models. Through an exploratory data
analysis or an analysis based on the physical processes
generating the data, an exponential life distribution
model may be judged as appropriate for the analysis of
the data. Specifically: where lambda is the unknown
constant failure rate. The vertical bar in $F(x/\lambda)$
indicates that we are conditioning on the parameter
lambda; i.e., for specified lambda the distribution is
exponential with failure rate lambda. The corresponding
density is $F(x/\lambda) = \lambda \exp -\lambda x$, $x > 0$.

ABSTRACT: (U) From the publications (in many cases from the figures) it is seen that incommensurate chains give a surprisingly good account of the following dozen measurements: both components of complex ac conductivities as functions of field and frequency; in both metallic and semiconducting CDW materials; dc characteristics; scaling of ac and dc conductivities; elastic properties - Young's Modulus and Q-factor as functions of voltage; bulk oscillations; and both amplitude and phase of both the second and third order mixing properties. In addition, incommensurate chains have been seen to exhibit complete mode locking over the entire range of dc fields and external frequencies. Keywords: Sliding density waves; Sliding potential.

ABSTRACT: (U) As part of the AFOSR Fast Algorithms Initiative, the project focused on the design of parallel algorithms and the related software design problems associated with multiprocessor systems. The research work was divided into two phases. The primary emphasis of the first phase was to study new algorithm ideas for solving the large numerical linear algebra problems associated with two and three dimensional elliptic P.D.E. problems. The work in the second phase of the research was directed toward understanding the software mechanisms needed to map these algorithms to existing parallel computers. In the following paragraphs we detail our work in both areas.

DESCRIPTORS: (U) *COMPUTER PROGRAMS, *PARALLEL PROCESSING, *ALGORITHMS, MULTIPROCESSORS, COMPUTERS, PARALLEL ORIENTATION, COMPUTATIONS.

SUPPLEMENTARY NOTE: Revision of report dated Jul 86, AD-A174 961.

ABSTRACT: (U) Heteroscedastic regression models are used in fields including economics, engineering, and the biological and physical sciences. This paper studies variance function estimation in a unified way, focusing on common methods proposed in the statistical and other literature, in order to make both general observations and compare different estimation schemes. There are significant differences in both efficiency and robustness for many common methods. A general theory is developed for variance function estimation, focusing on estimation of the structural parameters and including most methods in common use in our development. The general qualitative conclusions are these. First, most variance function estimation procedures can be looked upon as regressions with responses being transformations of absolute residuals from a preliminary fit or sample standard deviations from replicates at a design point. The former is typically more efficient, but not uniformly so. Secondly, for variance function estimates based on transformations of absolute residuals, we show that efficiency is a monotone function of the efficiency of the fit from which the residuals are formed at least for

symmetric errors. Our conclusion is that one should iterate so that residuals are based on generalized least squares. Finally, robustness issues are of even more importance here than in estimation of a regression function for the mean. The loss of efficiency of the standard method away from the normal distribution is much more rapid than in the regression problem.

UNCLASSIFIED REPORT

ABSTRACT: (U) A simple linear calibration function can be used over a wide concentration range for the Inductively Coupled Plasma (ICP) spectrometer due to its linear responses. The random errors over wide concentration ranges are not constant, and constant variance regression should not be used to estimate the calibration function. Weighted regression techniques are appropriate if the proper weights can be obtained. Use of the calibration curve to estimate the concentration of one or more unknown samples is straightforward, but confidence interval estimation for multiple use of the calibration curve is less obvious. A method is described for modeling the error along the ICP calibration curve using the estimated parameters from the fitted model to calculate weights for the calibration curve fit. Multiple and single-use confidence interval estimates are obtained and results along the calibration curve are compared.

ABSTRACT: (U) Cyclotron resonance with observed electric
field fluctuations is responsible for production of the
oxygen ion conics that are observed by the Dynamics
Explorer 1 satellite in the central plasma sheet region
of the Earth's magnetosphere. The ion velocity
distribution is described by a quasi-linear diffusion
equation which is solved by the Monte Carlo technique.
The acceleration produced by the observed wave spectrum
agrees well with the ion observations, in both form and
magnitude. This represents the first successful
comparison of an observed conic with any theoretical
model. Keywords: Ionospheric modeling; Ion acceleration;
Broadband electromagnetic turbulence.

ABSTRACT: (U) This project concentrated on issues of nonlinear control design, with an emphasis on digital systems and symbolic methods. One area of effort was that of studying the effect of the use of sampling on the controllability and observability of nonlinear continuous systems as well as on recently developed linearization techniques. This is closely related to work on discrete-time controllability, also in progress under the grant. Another area dealt with a new method for automatic gain scheduling, for which a computerized design is now available. Experimental results are also described. Keywords: Sampling discrete time control systems.

ABSTRACT: (U) The photochemistry of methylbenzyl benzyl ketones (ACOB) in the presence of pentasil zeolites follows strikingly different pathways due to the location of the absorbed ketone. The product distribution, in terms of the cage effect (efficiency of geminate radical combination), demonstrates the effects of sorption and diffusion on the radical species produced by photolysis. p-ACOB is readily adsorbed within the pentasil framework and produces p-AB as the primary product. In contrast, the photolysis product distributions of o-ACOB can be dramatically varied depending upon the extent of its adsorption into the framework. By addition of a nonreactive titrant, such as water, after the ketone adsorption, the photolysis product distributions can be systematically varied depending upon the aluminum content of the framework. The observed results are completely described by considerations of (a) the size and shape sorption of the pentasil zeolites, (b) the sorption of water by the hydrophilic sites of the pentasil zeolites (which depend upon the framework aluminum content), and (c) the hydrophobic characteristics of pentasil channels which do not contain framework aluminum. Keywords: Zeolites; Pentasil; Molecular sieves; Cage effects;

ABSTRACT: (U) Since October 1983, a new HF radar facility has been operated from Goose Bay, Labrador, for the purpose of studying high-latitude ionospheric irregularities. This paper presents autocorrelation functions of the backscattered signals from these irregularities and shows how these are processed to yield information on the drift velocities of the irregularities. Since the radar is typically operated in an azimuth scan mode, the Doppler data derived from the autocorrelation functions may be used to study the two-dimensional structure of the irregularity drift. A procedure is presented for this analysis, and it is shown that the results are reasonably accurate during periods in which the irregularity drift is approximately uniform. However, if the flow is nonuniform, as it is in the vicinity of the cusp and in the midnight local time sector, then the procedure leads to erroneous results. The implication are considered that these results have on azimuth scan measurements of plasma drift with incoherent scatter radars, and possible ways are presented in which measurements might be made under nonuniform flow conditions.

ABSTRACT: (U) A procedure has been developed for treating the dynamic interaction between a separated wake and a surface undergoing an unsteady motion. The basis of the method is an unsteady (time-stepping) panel method coupled with unsteady integral boundary layer codes. Pilot codes have been developed for both two and three dimensional conditions. Results presented here are mainly from the two-dimensional code in which the various routines for controlling the dynamic wake model have been developed. Some viscous/inviscid three-dimensional results are shown. The long term objective is to treat complete aircraft configurations through high angle-of-attack maneuvers. Keywords: Unsteady; Time stepping calculations; Dynamic separated wake model; Coupled viscous inviscid calculations.

ABSTRACT: (U) An electrophysiological stimulation
paradigm similar to one that produces Pavlovian
conditioning was applied to synaptic inputs to pyramidal
neurons of hippocampal brain slices. Persistent synaptic
enhancement was induced in one of two weak synaptic
inputs by pairing high-frequency electrical stimulation
of the weak input with stimulation of a third, stronger
input to the same region. Forward (temporally overlapping)
but not backward (temporally separate) pairings caused
this enhancement. Thus hippocampal synapses in vitro can
undergo the conditional and selective type of associative
modification that could provide the substrate for some of
the mnemonic functions in which the hippocampus is
thought to participate. (Reprints)

UNCLASSIFIED REPORT

ABSTRACT: (U) Singular control problems with diffusion or Wiener process systems have been occurring with increasing frequency as models of a wide variety of applications; e.g., storage, inventory, finite fuel, consumption and investment, limits of impulsive control problems, etc. Here, the increment of the control force is not of the usual form $u(t)dt$, but is the differential of a non-decreasing and suitably adapted process. The models used (Wiener or diffusion processes) are only approximations in some sense to some 'physical' process - perhaps a 'wideband' noise driven system or a suitably scaled discrete parameter process. The optimal controls for these 'physical' processes are usually nearly impossible to obtain. Thus, it is of considerable interest to know whether the optimal (or delta-optimal control for the diffusion model is 'nearly' optimum when applied to the physical problem, when compared to the optimal or delta optimal control for the latter problem. This is true, under broad conditions. The discounted and average cost per unit time problems are treated. The main methods are those of weak convergence theory.

ABSTRACT: (U) Eleven papers were published documentary work performed under this grant, and 14 lectures were presented. Several mathematical results were obtained concerning the performance of protocols for packet switching, local area networks, and satellite communications. In particular, results concerning the stability of the exponential backoff protocol were obtained.

SUPPLEMENTARY NOTE: Pub. in Jnl. of the Chemical Society, Faraday Transactions 2, v83 p639-646 1987.

ABSTRACT: (U) Visible chemiluminescence in the spectral range 200-900nm has been measured for the reactions of F atoms with allyl iodide, moniodobenzene, hexa-iodobenzene and ortho-, meta- and para-iodotoluene studied at reduced pressures (ca. 0.6 mbar). Emission was observed from electronically excited IF* (B), HCF(A), CH*(A) and C(d) and from vibrationally excited HF. Vibrational populations and rotational temperatures were obtained for the diatomic emitters. There is a strong interdependence of the relative intensity of HCF emission and the intensities of CH and CH, suggesting that their production may involve competing reactions of the same species. The similarity in the types of emitters and their states of formation leads to the conclusion that the same reactions, probably involving very simple species, take place in all cases. Keywords: Chemiluminescence, Iodine Monofluoride, Fluorine atoms, Organic iodides.

ABSTRACT: (U) Our studies concerning the carbonylation chemistry of early transition metal silyl complexes have led to the discovery of Cp*Cl Ta (n-COSiMe) (1, Cp* = n-C Me), a reactive n silaacyl derivative. Recently we have found that 1 readily reacts with Lewis bases to form complexes of the type Cp*Cl Ta OC(L)SiMe, in which the Lewis donor binds to the silaacylcarbon atom. Here we report the preparation and characterization of the trimethyl phosphite adduct Cp*Cl Ta ?n -OC(SiMe)P(OMe) (2) and its spontaneous Arbuzov-like dealkylation to MeCl and Cp*Cl TaN-OC(SiMe)P(OMe)O (6). The latter compound, which has been characterized by X-ray crystallography, contains an unusual n-phosphonatosilaacy (2-) ligand. The dealkylation of trialkyl phosphites is promoted by a number of transition metal complexes. Dealkylation is usually preceded by coordination of phosphite to the transition metal. In a few cases this process appears to follow attack of the phosphite onto an electrophilic ligand bound to metal, as in the reaction reported here.

ABSTRACT: (U) This project investigated parallel/vector
supercomputer architectures for solving Air Force
problems, which demand the solution of partial
differential equations (PDEs). We have developed an
orthogonal multiprocessor (omp) architecture for
efficiently implementing the SLOR and ADI methods in
solving PDEs. Another parallel PDE machine architecture,
called the V-tree multiprocessor, has been developed for
mapping the multigrid algorithms. This V-tree is shown to
be more effective than the well-known hypercube and mesh
architectures. Both the omp and the V-tree architectures
can demonstrate linear speedup by exploiting parallelism
and vectorization. Continued efforts are needed to expand
these initial studies into real hardware experiments and
software simulations to verify the theoretical
predictions on speedup performance.

ABSTRACT: (U) The Goose Bay high frequency radar can be
operated in a mode that allows the study of the temporal
and spatial behaviour of pulsating phenomena with a time
scale of minutes. On November 28, 1983, an event occurred
during which long period pulsations were observed in the
radar data. At this time, the field of view of the radar
included a region of the cleft immediately to the east of
the cusp. Combination of the radar data with HILAT
magnetometer data had allowed the identification of the
regions of the magnetosphere that mapped to the radar
field of view. Pulsations with 10-min and 15-min periods
were seen in a region mapping to the interior of the
magnetosphere. They had high azimuthal wave number (17-25)
and propagated eastward with a speed greater than 1 km/s.
At the same time, eastward drifting patches of
backscatter with a similar speed were seen in the region
of antisunward convection that mapped either to the solar
wind or the low-latitude boundary layer. A possible
interpretation is that antisunward disturbances
propagating along the magnetospheric boundary were
driving surface waves within the magnetosphere. Possible
types of disturbance that could cause such surface waves
are flux-transfer events or Kelvin-Helmholtz waves.

ABSTRACT: (U) The construction and performance of a
photoelectron spectrometer designed for the vapor-phase
study of high-temperature species is described. An
inductively heated furnace is used to produce atoms and
molecules in the vapor phase at furnace
temperatures > 2000K. Electrical interference is eliminated
using pulsed heating and gated electronics. A
microchannel plate phosphor silicon-intensified-target
camera detector is used for rapid data acquisition to
minimize problems caused by time-dependent contamination
in the ionization region. A dedicated, menu-driven,
firmware-based interface, with key pad control, is
utilized. The TV monitoring of the photoelectron line
images and use of a video window to select data allow
optimum spectral conditions to be preserved during and
experiment. Results show reductions in data acquisition
times of up to 90 compared to equivalent single-channel
detector experiments.

SUPPLEMENTARY NOTE: Pub. in Physical Review A, v35 n7 p3102-3108, 1 Apr 87.

ABSTRACT: (U) An algorithm for the 3-Satisfiability problem is presented and a probabilistic analysis is performed. The analysis is based on an instance distribution which is parameterized to simulate a variety of sample characteristics. The algorithm assigns values to variables appearing in a given instance of 3-Satisfiability, one at a time, using the unit clause heuristic and a maximum occurring literal selection heuristic; at each step a variable is chosen randomly from a subset of variables which is usually large. The algorithm runs in polynomial time and it is shown that the algorithm finds a solution to a random instance of 3-Satisfiability with probability bounded from below by a constant greater than zero for a range of parameter values. The heuristics studied here can be used to select variables in a Backtrack algorithm for 3-Satisfiability. Experiments have shown that for about the same range of parameters as above the Backtrack algorithm using the heuristics finds a solution in polynomial average time.

ABSTRACT: (U) A time consistent global pressure relaxation procedure of the unsteady, compressible, reduced Navier Stokes equations is presented. The shock capturing capability of the procedure is investigated with different forms of pressure gradient splitting. An efficient conservative method for capturing shocks is detailed. The transient behavior of laminar, high Reynolds number, low subsonic flow past a sine-wave airfoil geometry is analyzed using the new reduced Navier Stokes based algorithm. These solutions are compared with steady and unsteady results previously obtained with a modified interacting boundary-layer procedure. The strong influence of grid refinement and the type of differencing of the steamwise convection term on the existence or stability of separated laminar solutions is reaffirmed. More stable turbulent flow results are also presented. Finally, an unsteady solution for the flow past a finite flat plate at incidence is described in order to demonstrate the time accuracy of the algorithm.

ABSTRACT: (U) A projection theorem is obtained for the class of far field patterns of the acoustic transmission problem corresponding to time-harmonic incident plane waves propagating in arbitrary directions. This projection theorem depends on the eigenvalues of a new class of boundary value problems associated with the transmission problem. This projection theorem and the theory of Herglotz wave functions, is used to derive two distinct optimization schemes for solving the inverse transmission problem. Numerical examples are then given showing the practicality of the second of these two methods for solving the inverse transmission problem.

ABSTRACT: (U) One-step algorithms are presented for two
classes of structured stochastic games, namely, those
with additive rewards and transitions and those which
have switching controllers. Solutions to such classes of
games under the average reward criterion can be derived
from optimal solutions to appropriate bilinear programs.
The validity of using bilinear programming as a solution
method follows from two preliminary theorems, the first
of which is a complete classification of undiscounted
stochastic games with optimal stationary strategies. The
second of these preliminary theorems relaxes the
conditions of the classification theorem for certain
classes of stochastic games and provides the basis for
the bilinear programming results. Analogous results hold
for the discounted stochastic games with the above
special structures. (Reprints)

ABSTRACT: (U) Contents: Effect of Pole Pieces on the
Axial Magnetic Field in Traveling Wave Tubes; An
Analytical Study of Two-Stage Light Gas Gun Performance;
A Low-Cost Local Area Network for Desktop Computers;
Development of Prediction Models For Human Torque
Strength; The Role of Antioxidant In Preventing
Hyperbaric Oxygen Damage to the Retina; The Influence of
Melting and Reactant Consumption on Temperature
Transients in Spherical and Cylindrical Charges of EAK;
Geostrophic Adjustment in a Three Dimensional MESOSCAL
Numerical Model of the Atmosphere; Effect of Temperature
and Reactant Solution Upon The Rate of Gas-Phase Ion
Molecule Reactions; Effects of Nuclear Radiation on the
Optical Characteristics of Laser Components; Computer
Simulation of Aircraft Surface Dynamics; Computation of
Transonic Projectile Aerodynamics; Use of Bayesian
Decision Theory in Assessing the Portability of Ground
Water Based Drinking Water Supplies; Design of a Digital
Electronic-Warfare Passive Receivers; Dual Channel FFT
Systems Analysis Facility for Assessing Integrated
Communication Systems; Far Infrared Absorption Profiles
for Distributed Shallow Donors in GAAS-GAALAS
Heterostructures.

UNCLASSIFIED REPORT

ABSTRACT: (U) There has been considerable disagreement about how best to estimate the parameters in Michaelis-Menten models. This document points out that many fitting methods are based on different stochastic models, being weighted least squares estimates after appropriate transformation. The authors propose a flexible model which can be used to help determine the proper transformation and choice of weights. The method is illustrated by examples. Keywords: Nonlinear regression; Lineavever Burke transformation.

DESCRIPTORS: (U) *WEIGHTING FUNCTIONS, ESTIMATES, LEAST SQUARES METHOD, MATHEMATICAL MODELS, FITTING FUNCTIONS(MATHEMATICS), PARAMETERS, NONLINEAR ANALYSIS, REGRESSION ANALYSIS, STOCHASTIC PROCESSES, WEIGHT.

IDENTIFIERS: (U) Lineavever Burke models, Michaelis-Menten parameters.

SUPPLEMENTARY NOTE: Pub. in Quant. Spectrosc. Radiat. Transfer, v36 n5 p425-440 1986.

ABSTRACT: (U) Calculations have been made of O₂ absorption and fluorescence in the Schumann-Range B from X band system for excitation by a broadband argon fluoride excimer laser at 193nm. Results are presented for line strengths, spectral absorption coefficients, relative fluorescence spectra, total fluorescence and integrated absorption coefficients. The calculations have been performed for 300, 500, 1000, 1500 and 2000 K. a range of temperatures typically found in combustion flows. The absorption coefficients and fluorescence yields found are very large enough to encourage use of argon fluoride lasers for O₂ measurements in a variety of flows.

Keywords: Laser, Fluorescence, Imaging oxygen, Excimer, Absorption.

DESCRIPTORS: (U) *ABSORPTION, *ARGON, *FLUORIDES, *OXYGEN, ABSORPTION COEFFICIENTS, ABSORPTION SPECTRA, COMBUSTION, FLOW, FLUORESCENCE, HIGH TEMPERATURE, IMAGES, INTEGRATED SYSTEMS, LASERS, SPECTRA, STRENGTH(GENERAL), TEMPERATURE, X BAND, YIELD, REPRINTS.

UNCLASSIFIED REPORT

ABSTRACT: (U) This document examines the paths of the stable fields that are the analogs of index-beta Gaussian fields. The author finds Holder conditions on their paths and finds the Hausdorff dimension of the image, graph, and level sets when we have local nondeterminism, generalizing the Gaussian results. Keywords: inversion; random variables.

UNCLASSIFIED REPORT

ABSTRACT: (U) The paper presents some recently obtained results on the nonlinear filtering problem for infinite dimensional processes. The optimal filter is obtained as the unique solution of certain measure valued equations. Robustness properties - both pathwise and statistical - are given and a preliminary result shows consistency with the stochastic calculus theory. Applications to random fields and models of voltage potential in neurophysiology are briefly discussed. Keywords: Markov processes; white noise.

UNCLASSIFIED REPORT

ABSTRACT: (U) A generalized shot noise in Banach spaces is defined as the a.s. limit of certain centered sums of dependent random vectors; and, a necessary and sufficient condition for its existence is given. As an immediate application, the LePage-type series representations of infinitely divisible random vectors are obtained.

Keywords: Stochastic processes; Convergence; Hilbert space.

DESCRIPTORS: (U) *STOCHASTIC PROCESSES, *POISSON DENSITY FUNCTION, BANACH SPACE, HILBERT SPACE, SHOT NOISE, VECTOR

ABSTRACT: (U) This document describes a strictly stationary sequence of random variables which satisfies the strong mixing condition (also known as uniform or alpha-mixing). Keywords: Normalizing functions; Weak convergence; Continuous distribution; Extreme values; Point processes.

ABSTRACT: (U) It is well known that point process methods can be applied effectively to study certain types of problems in statistical extreme value theory. Consider a strictly stationary sequence of random variables $(x_i \text{ sub } j)$ indexed by the set of integers $I=Z$. One can define a number of interesting point processes in one dimension by recording the positions where extreme values occur. For example, an extremal process typically is one that records the indices (properly normalized) at which record values of $x_i \text{ sub } j$, x_i or $\text{sub } 2$ occur, and an exceedance point process considered by Leadbetter consists of the set of points $j.n: x_i \text{ sub } j > w \text{ sub } n$, where $\text{sub } n$ is a suitable sequence of constants. For this type of processes, Poisson or compound Poisson convergence results can often be derived under suitable mixing conditions. Keywords: Weak convergence.

ABSTRACT: (U) Translates of symmetric stable and other p sub th order processes are considered. An upper bound for the set of admissible translates of a general p sub th order process is presented, which is a partial analog of the reproducing kernel Hilbert space of a second order process. For invertible stable processes a dichotomy is established, i.e. each translate is either admissible or singular, and the admissible translates are characterized. As a consequence, most continuous time moving averages and all harmonizable processes with nonatomic spectral measure have no admissible translate; and the admissible translates of a general harmonizable process are characterized. The translates of a mixed autoregressive moving averages stable sequence are shown to coincide with those of the Gaussian case.

ABSTRACT: (U) This is a reprint version of an article written at the request of the International Statistical Review. The article is organized in three main sections. The first of these is a brief overview of Harald Cramer's life and career. The second (and main) section is an account of his work in Probability and Statistics, with historical perspective where possible. The third, final section contains personal comments and recollections from the author's own contacts with Harald Cramer. These are intended to complement the description of the career and scientific contributions of Cramer, with some glimpses of his personal qualities. Keywords: Stationary processes; Insurance risk; Markov processes.

ABSTRACT: (U) A stochastic control problem is obtained as a small noise approximation to a deterministic optimal control problem. Two classes of admissible controls are considered and the optimal control policies are explicitly determined for a each admissible class. The larger admissible class contains controls referred to as singular stochastic controls. For this class, the cumulative effect of control has bounded variation trajectories. The smaller admissible class contains the standard stochastic controls whose cumulative effect has absolutely continuous trajectories. These controls are referred to as absolutely continuous controls. The optimal singular control provides a cost strictly smaller than the minimum cost achievable when only absolutely continuous stochastic controls are admissible. In particular, this shows that is not always possible to approach the optimal cost for singular control is only the standard stochastic control policies are admissible. Keywords: Hamilton-Jacobi-Bellman equation.

ABSTRACT: (U) Free boundary problems are defined and illustrated by several problems in mechanics. First the problem of finding the free surface of a liquid in hydrostatic equilibrium is considered. Then the effect of surface tension is taken into account. Finally the contact of an inflated membrane, such as a balloon or tire, with a solid surface is formulated. This problem is solved by the method of matched asymptotic expansions when the contact area is small. Keywords: reprints; hydrostatics; surface tension; axial symmetry.

ABSTRACT: (U) The objective of this research investigation was to determine, experimentally and analytically, the physical mechanisms that control the behavior of continuous, laser sustained plasmas. The principle questions involve the effects of a forced convection environment and optical geometry on the stability, fractional power absorption, plasma structure, and fluid mixing. A continuous, 1.5 kW, axial flow, carbon dioxide laser was used to create the LSP in a cylindrical quartz flow channel. The convection flowfield surrounding the plasma was controlled by the volume flow through the test chamber, and the optical geometry was determined by the unstable oscillator output mode of the laser and the focal length of the lens. Digital images of the plasma in a selected narrow wavelength interval were obtained using a CID digital camera and a VICOM digital image processing computer that were calibrated for absolute radiance. These images were then Abel inverted to give a spatial plasma emission coefficient which determined the spatial distribution of the plasma temperature. These measured temperature fields were then used to calculate the laser power absorption in the plasma and the power lost from the plasma through optically thin emission. More than one hundred sets of data were obtained for argon plasmas at nominal pressures from 1.5 to 3 atmospheres and incident flow velocities from 0.4 to 4.0 m/s.

ABSTRACT: (U) An analysis was developed describing the spatial parallel flow development of disturbances that are introduced into an incompressible laminar boundary layer by a vibrating ribbon at the wall. The dominant mode is corresponding to the eigenmode of the flow at the ribbon frequency, as found by Gaster, but the solution technique does not require the questionable assumptions previously invoked. Analysis of the compressibility introduces additional complexities, including the stagnation enthalpies of the two streams, and admits influences of higher acoustical modes. Keywords: Compressible free shear layers.

ABSTRACT: (U) A mathematical model is presented for determining the composition of extended solid solution formed due to rapid cooling in laser cladding. This model considers a diffusion mechanism for mass transport in a one-dimensional semi-infinite molten pool of the cladding material from which heat is removed by conduction through a one dimensional semi-infinite solid substrate. The rate of solidification has been obtained by modeling the cooling process as a composite medium heat transfer problem. The discontinuity of the concentration field has been simulated using a nonequilibrium partition coefficient, and then a nonsimilar exact solution for the mass transport equation has been obtained using a set of similarity variables which has been derived using Lie group theory.

ABSTRACT: (U) Problems arising in the area of nonlinear vibrations were studied. Essentially equations such as that for a periodically forced, damped pendulum are capable of exhibiting behavior which was unsuspected even 10 years ago and the principal investigator was in the forefront to the effort to explain these mysteries. It was he who coined the term 'chaos' and the students and publications here identified are confined to that topic. Dr. Yorke reports on work to determine the factual dimension of attracting sets for differential equations together with some vigorous results on the dependence of such sets on equation parameters.

ABSTRACT: (U) The objective of this research is to clarify the mechanisms responsible for the suppression of soot in flames by fuel additives. Measurements are limited to well-defined hydrocarbon/air prevaporized liquid- and gaseous-fueled flames. Emphasis is given to ferrocene in a diffusion flame fueled by prevaporized iso-octane. Nonperturbing laser/optical diagnostic techniques are used to relate changes in soot particulate size, number density, and volume fraction to additive concentration. Ferrocene is observed to suppress a visible soot plume completely and, in general, to intervene at a late combustion stage. Suppression is due to both size and number density reduction, which suggests that ferrocene enhances the oxidative burn-out of soot. In contrast, at an early combustion stage nearer the burner lip, a slight enhancement of soot observed with ferrocene seeding. Keywords: Additive, Ferrocene, Flame, Soot.

ABSTRACT: (U) A variety of scientific investigations of outstanding interest are now possible using an atomic physics facility (APF) based on the combination of an undulator or wiggler a: a high-brilliance synchrotron light source, a synchrotron storage ring for heavy ions, and a tandem accelerator or other source of highly ionized atoms for filling the storage ring. The APF opens dazzling new vistas for qualitatively new experiments in atomic physics and related fields since it gives improved reaction rates, provides refined energy resolution, and produces copious quantities of multiply ionized atoms in well-defined states. The APF represents a way of combining new techniques into a powerful, well-coordinated facility to deal comprehensively with the new atomic physics. The science that can be done with the APF is discussed mainly from the general view of what can be done with synchrotron radiation. The storage ring can also be used completely independently with lasers or to study ion-electric, ion-atom, or ion-ion interactions. Together, electron and heavy-ion storage rings provide an extraordinarily large number of ways of preparing and probing atoms and molecules. By employing complementary experimental methods at a single facility, the APF makes it possible to choose the very best experimental

SUPPLEMENTARY NOTE: Pub. in Jnl. of Physical Chemistry, v91 n9 p2230-2232 1987.

ABSTRACT: (U) The adsorption of benzene on the Ni (100) and the Ni (111) crystal faces was compared in order to investigate the effect of crystallographic orientation on the interaction of benzene with nickel. Temperature programmed reaction (TPR) was used to characterize adsorption bond strengths and determine product distributions. Benzene was found to adsorb 44 kJ/mol less strongly on the Ni(111) plane than on the Ni(100) surface. Di hydrogen evolution formed after decomposition of benzene was similar for both surfaces. Benzene chemisorption was modeled by using extended Huckel theory (EHT), a semiempirical molecular orbital method. The calculations predict bonding of benzene over a three-fold hollow site on Ni(111). Multicenter bonding of the benzene carbon atoms with the nickel atoms is indicated by the calculations. The binding strength of benzene is controlled by the degree of overlap of the carbon orbitals with the nickel atom orbitals. Benzene binds more strongly to the Ni(100) surface because of the carbon pi orbitals can overlap with four nickel atoms on the fourfold hollow site, whereas on Ni(111) the carbon atoms are closely associated with only three nickel atoms on the threefold hollow site. Keywords: Nickel, Benzene, Extended Huckel theory, Molecular bonding.

ABSTRACT: (U) Coherent thin films of poly(bis(p-toluene sulfonate) diacetylene) were successfully formed by modified Langmuir-Blodgett techniques using two methods: (i) photopolymerization of the monomer film at the gas/liquid interface and then transfer to a solid substrate, and (ii) transfer of the monomer film to the solid substrate and subsequent photopolymerization on the substrate itself. The films thus obtained were characterized by traditional force-area isotherms while on pure water subphases. Segments were transferred at either 1 or 10 dyn/cm surface pressure, in different stages of photopolymerization, to glass or germanium substrates. The films on the substrate were characterized by the methods of multiple attenuated-internal-reflection infrared spectroscopy, ellipsometry, contact-potential measurement, and laser Raman spectroscopy. Our results show that the films are multimolecular and about 100 Å thick. Of special interest were the observation of significant anisotropy of oriented dipoles and the ability to obtain excellent spectral data for these very thin oriented films. Raman spectroscopic features are similar to those observed for the bulk polymer, even in the low-frequency region. Polarized Raman spectroscopy

ABSTRACT: (U) In this paper, the authors derived asymptotic joint distributions of the eigenvalues of some random matrices which arise under components of covariance model. Keywords: Eigenstructure analysis; Multivariate analysis; Analysis of variance.

ABSTRACT: (U) In a number of situations, the experimenter is confronted with the statistical analysis of the data which is binary in nature. For example, one may be interested in diagnosis of the disease on the basis of symptoms. The reliability of complicated systems can be studied by examining as to whether its components are functioning or not. In image processing, a picture is classified on the basis of two grey levels like white and black using some threshold value. We may assign a score of 1 or 0 according as the grey level is white or black respectively. So, it is important to study the problems of estimation of multivariate binary density. Cencov expressed continuous multivariate density as a series of orthonormal functions. Bahadur expressed the multivariate binary density as a series. Ott and Kronmal expressed the density as a series involving Walsh functions. Liang and Krishnaiah also expressed the density in terms of Walsh functions but the coefficients in their series are different from those used by Ott and Kronmal. This paper is a continuation of the work done by Liang and Krishnaiah.

UNCLASSIFIED REPORT

ABSTRACT: (U) The concepts of metrics and distances are fundamental in problems of statistical inference and in practical applications to study affinities among a given set of populations. A statistical model is specified by a family of probability distributions, described by a set of continuous parameters known as the parameter space. This model possesses some geometrical properties which are induced by the local information structures of the distributions. In particular, the Fisher information matrix of the given family of distributions gives rise to a Riemannian metric over the parameter space, whose geodesic distance, known as the Rao distance, plays a major role in the multivariate statistical techniques. For the family of multivariate normal distributions with fixed shape but varying locations, this distance reduces to the well-known Mahalanobis distance. This document refers to Burbea and Rao for more details on these concepts and their derivations. An interesting statistical model is provided by the family of elliptic distributions whose density functions have elliptical contours and which include the multivariate normal distributions as a subfamily. This paper studies the information metric associated with an elliptic family whose shape varies linearly.

ABSTRACT: (U) Measurements of structure angle in a
supersonic turbulent boundary layer with zero and adverse
pressure gradients are presented. Conditionally sampled
measurements of u, v , and w are presented along with
quadrant analysis of the turbulent fluctuations. The
latter suggests ambiguities associated with the
interpretation of VITA measurements. Preliminary results
of experiments on artificially generated hairpin vortices
are also discussed. Measurements indicate a high degree
of similarity between the signatures of these hairpin
structures and ensemble averaged events in the turbulent
boundary layer. Keywords: Turbulence, Boundary layer,
Supersonic Flow.

ABSTRACT: (U) In stochastic scheduling and optimal
maintenance problems that have been considered in the
literature, the optimization criterion used has often
been equivalent to minimizing the expected first passage
times to a set of states. A typical method used in
establishing the optimality of a certain policy is the
method of successive approximations on the appropriate
dynamic programming functional equations. As an
intermediate result, this technique often involves the
optimality of the pertinent policy for all finite horizon
versions of the problem. This paper characterizes
stochastically optimal policies as policies that process
a similar property, i.e. these are optimal in expectation
for all members of a sequence of appropriately defined
finite horizon problems. The authors use this
characterization to establish the stochastic optimality
of relevant policies for the optimal repair allocation
for a series system problem and for a scheduling problem.

ABSTRACT: (U) Based on right censored data from a lifetime distribution F sub 0, a modification of the kernel quantile estimator is proposed. The advantage of this estimator is that the data play a role in the degree of smoothing of the estimator while retaining the desirable features of the kernel estimator. Convergence in probability and almost sure convergence of the estimator are discussed. Some examples are given which illustrate the differences between this modified estimator and the fixed-bandwidth kernel quantile estimator for randomly right-censored data. Keywords: Random censoring; Product-limit quantile function; Kernel type quantile estimator; Nonparametric quantile estimation.

ABSTRACT: (U) The principle object of the research was to provide a better understanding of the behavior of the soil-structure interaction phenomena associated with buried conduits subjected to airblast loads. A parametric study was performed to experimentally determine the effects of airblast loads on 4-in diameter micro-concrete pipes, embedded horizontally in a dry sand. The parameters varied in the study included the gravity level, the applied airblast pressure level, the relative density of the dry sand, burial depth of the structure, and the relative stiffness between the structure and the soil. A geotechnical centrifuge was used to create the proper in-situ stress conditions in the sample during each test. Dynamic stress gages were utilized to measure the applied airblast on the sample surface, the normal stresses acting at the soil-pipe interface, and in the free-field conditions. Proximitors positioned inside of the structures were used to measure the resulting deflections. The results of the experimental study verified the importance of testing models at increased gravity levels, and determined the feasibility of the dynamic stress gages for measurement of contact and free-field stresses.

ABSTRACT: (U) Soil-Structure interaction under blast loading was investigated both experimentally in 10 g-ton centrifuge and analytically by finite element simulation. In the centrifuge experiments, circular pipes made of micro-concrete were buried in a dry sand and tested in the centrifuge to simulate the effects of gravity-induced overburden stresses which played a major role in controlling the soil stiffness and, subsequently, the response of the pipe. The blast loading was simulated by a pressure pulse generated by rupturing a burst disc in an impact generator. Surface stress gages and contact stress gages both made of polyvinylidene fluoride were built and calibrated to measure air blast magnitudes and contact pressures. The centrifuge experiments provided insight into the dynamic response of buried pipes and a data base for the verification of numerical results. These results were obtained by linear and non-linear finite element analyses of the experiments duplicating the surface overpressure loading. The suitability of constitutive relations for both soil and micro-concrete were verified by comparing test results and analysis. The effects of soil arching around the buried pipe was also

ABSTRACT: (U) Product state distributions of thermal energy ion-molecule reactions are determined by the sensitive optical methods of infrared chemiluminescence and laser-induced fluorescence detection. Experiments to obtain detailed vibrational state populations are carried out in a flowing afterglow ion source. Product state information is obtained for a series of proton transfer reactions and charge transfer reactions, which reveals many aspects of the dynamical behaviors of these processes. Measurements are also presented for polyatomic ion-molecule reactions, for optically-determined rates of ion collisional excitation and deactivation, and on visible chemiluminescence yields and branching fractions for reactions important in the aurora. Keywords: Aurora; Flowing afterglow; Infrared chemiluminescence; Ion molecule reactions; Laser; Product states.

ABSTRACT: (U) The authors present a method for constructing an orthonormal basis for a symmetry class of tensors from an orthonormal basis of the underlying vector space. The basis so obtained is not composed of decomposable symmetrized tensors. Indeed, we show that, for symmetry classes of tensors whose associated character has degree higher than one, it is impossible to construct an orthogonal basis of decomposable symmetrized tensors from any basis of the underlying vector space. We end with an open problem on the possibility of a symmetry class having an orthonormal basis of decomposable symmetrized tensors. (Reprints).

ABSTRACT: (U) In mammals, a group of neurons localized in an area of the brainstem called the locus coeruleus utilize norepinephrine as their neurotransmitter and are believed to be important in attention, vigilance, anxiety, and arousal. Studies supported by this grant over the past 2 1/2 years explored these issues by means of chronic single unit recordings in unrestrained and unanesthetized cats. The work has been highly productive and has resulted in a number of major findings, most of which have been published or will be published within the next six months. We have completed a detailed analysis of the response of locus coeruleus-noradrenergic (LC-NE) neurons to repetitive presentation of simple sensory stimuli and how this response is altered by systemic administration of anxiolytic and anxiogenic drugs. We have also finished a study which examined the activity of these neurons during appetitive and aversive conditioning. In our most comprehensive investigations in the series of environmental and physiological challenges (stressors). Overall, our experiments indicate an important role for this system in vigilance and bioreactivity, especially in situations that can be regarded as challenging or successful to the organism.

ABSTRACT: (U) Both laboratory and in-flight studies were carried out in order to evaluate the utility and feasibility of EEG monitoring as a means of identifying central nervous system correlates of performance and G-force effects during military flight operations. Four studies were conducted, two with controlled laboratory simulation, and two in actual flight during military training missions. Data analysis focused on EEG power-spectral density characteristics and their temporal modulation, specifically in sensorimotor and visual cortical areas. Several consistent findings emerged. During competent performance, a highly unique discrepancy appeared between left and right hemispheres in central 8-15 Hz activity. This pattern disappeared as performance degraded. The temporal modulation of this activity also reflected these changes. During high G-force situations, power at frequencies below 8 Hz was progressively and non-specifically enhanced. Continued competent performance, however, was still reflected by the pattern described above. These findings are discussed in terms of their neurophysiological implications.

ABSTRACT: (U) This report summarizes the activities at Boeing Computer Service Company from April 15, 1985 until August 15, 1986. Five tasks are defined in our analysis of quotient tree algorithms and frontal methods: analysis of multifrontal methods, creation of symmetric indefinite out-of-core minimal storage elimination schemes, analyses of quotient tree orderings, and completion of the Boeing-Harwell sparse matrix collection. (Keywords: linear equations; reordering algorithms; Choleski factorization; vector computers; parallel computers.

DESCRIPTORS: (U) *SPARSE MATRIX, *HEURISTIC METHODS, ALGORITHMS, ELIMINATION, LINEAR ALGEBRAIC EQUATIONS, PARALLEL ORIENTATION, STORAGE, VECTOR ANALYSIS.

IDENTIFIERS: (U) Vector computers, PE61102F, WUAFOSR2304A3.

ABSTRACT: (U) Thermal reaction of a hexane solution of octafluorocyclooctatetraene (OFOT) with either Co(Cp*)(CO)2 or Rh(Cp*)(C2H4)(Cp* = eta-C5Me5) in the dark afforded good yields of the complexes M(eta-C5Me5)-(1,2,5,6-eta-C8F8) (11a, M = Co; 11b, M = Rh). Photolysis of solutions of 11a, b at different temperatures afforded a photostationary 2.3:1.0 mixture of the starting complexes and the isomeric compounds M(eta-CMe5)(1,2,3,6-eta-C8F8) (12a, M = Co; 12b, M = Rh). The ratio of isomers is independent of M and the photolysis temperature. Heating each mixture in the dark results in quantitative conversion to pure isomer 11. One-electron reduction of 11a results in an ECE mechanism. The first electron-transfer step produces the radical anion 11a-, in which the mode of ligation of OFOT to cobalt is maintained and in which ESR studies show the half-filled orbital to be located primarily on the metal. Subsequent reaction of this radical anion occurs to give an electrochemically active product that was too unstable to characterize. Keywords: Fluorine compounds, Cyclic compounds.

IDENTIFIERS: (U) Quantile functions.

ABSTRACT: (U) A percept of global coherent motion can result from the combination of many different localized motion vectors. We report evidence of hysteresis in the perception of this global motion, obtained with random-dot cinematograms. The hysteresis characteristics are relatively robust with respect to changes in dot density, display area, and location. Changing the directional content of the stimulus, however, did alter the hysteresis profile in a manner consistent with a model incorporating cooperative interactions among direction-selective motion mechanisms. Our results lend further support to a cooperative interpretation of motion perception in random-dot cinematograms. Keywords: visual perception. (Reprints)

ABSTRACT: (U) The 42nd Symposium on Molecular Spectroscopy was convened at Ohio State University during the period 15-19 June 1987. Over 300 scientists attended, representing research organizations from the U.S. and fourteen foreign countries. Topical areas included

electronic characteristics of molecules, energy transfer, infrared and microwave spectra, liquid and solid state phenomena, laser spectra, Raman spectra, molecular beams, vibrational analysis, and experimental techniques. As planned, special emphasis was placed on the spectroscopy of van der Waals molecules, and there was a special session on probing and modeling the earth's atmosphere.

UNCLASSIFIED REPORT

ABSTRACT: (U) The author develops estimates for the parameters of Dirichlet-multinomial distribution (DMD) when there is insufficient data to obtain maximum likelihood or method of moment estimates known in the literature. We do, however, have supplementary beta-binomial data pertaining to the marginals of the DMD, and use these data when estimating the DMD parameters. A real situation and data set are given where the estimates are applicable. Keywords: Asymptotic properties.

DESCRIPTORS: (U) *ESTIMATES, *PARAMETRIC ANALYSIS, ASYMPTOTIC SERIES, MAXIMUM LIKELIHOOD ESTIMATION, METHOD OF MOMENTS.

IDENTIFIERS: (U) Multinomial distribution, PE61102F, WUAFOSR2304A5.

ABSTRACT: (U) The finite element method has three versions: the h-version, the p-version and the h-p version. In the h-version, increased accuracy is achieved by decreasing the mesh size h while keeping p , the degree of elements used fixed (usually $p = 1, 2, 3$). In the p-version, a fixed mesh is used while the degree p of elements are either uniformly or selectively increased to achieve accuracy. The h-p version is a combination of both. The standard h-version has been thoroughly investigated and many commercial and research programs are available. The p- and h-p versions are recent developments. There is only one commercial code, the system PROBE, and the first papers discussing theoretical aspects appeared only in 1981. The approximations of solutions of elliptic problems of order 21 over two-dimensional polygonal domains by the p-version of the finite element is investigated. Optimal rates of convergence are established for the case when elements possessing C continuity are used.

UNCLASSIFIED REPORT

ABSTRACT: (U) In estimating and comparing the rates of change of a continuous variable between two groups, the unweighted averages of individual simple least squares estimates from each group are often used. Under a linear random effects model, when all individuals have completed observations at identical time points these statistics are maximum likelihood estimates for the expected rates of change. However, with censored or missing data, these estimates are no longer efficient when compared to generalized least squares estimates. When, in addition, the right censoring process is dependent upon the individual rates of change (i.e., informative right censoring), the generalized least squares estimates will be biased. Likelihood ratio test for informativeness of the censoring process and maximum likelihood estimates for the expected rates of change and the parameters of the right censoring process are developed under a linear random effect models with a probit model for the right censoring process. In realistic situations, we illustrate that the bias in estimating group rate of change and the reduction of power in comparing group difference could be substantial when strong dependency of the right censoring process on individual rates of change is ignored. ABSTRACT: (U) This document proposes a class of bounded influence robust regression estimators with conditionally unbiased estimating functions given the design. Optimal estimators are found within this class. Applications are made to generalized linear models. An example applying logistic regression to food stamp data is discussed. Keywords: Asymptotic bias; Generalized linear models; Linear regression.

ABSTRACT: (U) The authors study the method of extended quasi-likelihood estimation of the variance function. This method is shown to be closely related to the method of pseudo-likelihood estimation as in Carroll & Ruppert (1982). Keywords: Asymptotic normality; Statistical inference; Heteroscedastic regression model.

ABSTRACT: (U) A number of important recent advances in econometric theory are related to the methods of truncated regression model - the regression model in which the range of the dependent variable is restricted to some interval of $(-\infty, \infty)$, usually the non-negative half-line, such as the income of an individual. Powell used the L sub 1-norm criterion with some modifications in estimating the regression coefficients in truncated linear models. He proved the consistency and asymptotic normality of his estimates under a set of conditions. On the other hand, Nawata's paper uses the ordinary L sub 2-norm (least square) criterion, along with a grouping and adjustment of the observed data. In his view, his method has the merit of easy computation compared with the method of Powell. This paper borrows the basic idea of Nawata in grouping and adjusting the observed data. But the authors make simplifications in the procedure of grouping, which enables us to make substantial extensions of the results of Nawata's paper under weakened conditions. **Keywords:** Linear median regression; Truncated regression; Parameters; Linearity.

ABSTRACT: (U) The set of all bivariate distributions with support contained in $((i,j); i = 1, 2 \text{ and } j = 1, 2, \dots, n)$ which are positive quadrant dependent is a convex set. In the paper, an algebraic method is presented for the enumeration of all extreme points of this convex set. Certain measures of dependence, including Kendall's tau, are shown to be affine functions on this convex set. This property of being affine helps us to evaluate the asymptotic power of tests based on these measures of dependence for testing the hypothesis of independence against strict positive quadrant dependence. Keywords: Multivariate analysis; Asymptotic; Random variables; Probability distribution functions.

ABSTRACT: (U) Several aspects of adaptive methods for partial differential equations implemented on vector and parallel computers were investigated on this effort. A new technique for mapping mesh points to processors in a static way has been developed, this takes advantage of the structure of the family of solutions without singling out any one solution. Three publications and two technical reports resulted from this effort, as well as two conference proceedings papers and four presentations. Papers included such titles as A comparison of domain decomposition techniques for elliptic partial differential equations and their parallel implementation, Local uniform mesh refinement on loosely-compiled parallel processors, and Dynamic grid manipulation for partial differential equations on hypercube parallel processors. ABSTRACT: (U) Under the current grant parallel hardware and systems software implemented on ZMOB in the previous year underwent extensive testing. A parallel problem solving system, PRISM (Parallel Inference System) implemented on the VAX/11-780 in the previous year was implemented on the PYRAMID and SUN machines. The initial version of PRISM uses a simulation of the ZMOB hardware, and has been fully tested and debugged. Experimental testing of PRISM on the simulated system was undertaken in the current year. In addition, several enhancements were made to PRISM to permit experimental analyses to be made, and to incorporate additional features to take full advantage of parallelism in a problem solving environment. The tracing and statistical gathering packages were extended. An AND-parallelism capability was added to achieve a second version of the PRISM system, and other features were added to the system to more fully exploit parallelism. A constraint solving machine was integrated with PRISM. In addition to the above, a general method to permit informative answers to be presented to a user has been developed. Theoretical results were obtained for circumscription and a method for computing in protected circumscription, using Horn clauses was developed. In the area of systems hardware and software, the ZMOB processor is now fully functional and in everyday use with 128 processors.

UNCLASSIFIED REPORT

ABSTRACT: (U) This paper studies the connectedness of 3 dimensional designs by reducing the dimension of designs from three to two. A new graphical method of determining the connectedness of designs is presented. The method is easier and simpler than the earlier known methods of Birkes, Dodge and Seely (1976) and Srivastava and Anderson (1970). A generalization of this method for 4 or higher dimensional designs is also discussed.

UNCLASSIFIED REPORT

ABSTRACT: (U) This work studied discharge processes in Knudsen mode (collisionless), thermionic energy converters. Mechanisms for reducing the effects of electron space charge in such devices are essential for thermionic converters to produce useful current and power densities. The mechanisms studied are: reduction of space-charge through a very close interelectrode gap (less than 10 microns); transport and retention of positive cesium ions generated by surface ionization; transport of positive cesium ions generated in an arc external to the electrodes; and the mechanism for enhanced current output due to a structured emitter in a mixed barium-cesium vapor. The experimental work used SAVTEC (Self-Adjusting, Versatile Thermionic Energy Converter) diode structures which were tested in a chamber containing 0.1 - 1.0 torr of cesium vapor. Comparison of measured volt-ampere curves with theory gave excellent agreement and indicated an interelectrode gap of 6.5 microns at an emitter temperature of 1250 K. A theoretical model of the collisionless thermionic diode was developed which included surface ionization, auxiliary ions from an external source, and trapping of charged particles in potential wells due to infrequent collisions. Studies showed that trapping of positive ions leads to a large,

beneficial increase in current density. Using a diffusion analysis to couple this model to models of collision-dominated discharges gave predictions of the performance of SAVTEC devices in the presence of an auxiliary discharge, and led to design criteria for electrode size in order for auxiliary ionization to be effective.

UNCLASSIFIED REPORT

ABSTRACT: (U) In stochastic scheduling and optimal maintenance problems that have been considered in the literature, the optimization criterion used has often been equivalent to minimizing the expected first passage times to a set of states. A typical method used in establishing the optimality of a certain policy is the method of successive approximations on the appropriate dynamic programming functional equations. As an intermediate result, this technique often involves, the optimality of the pertinent policy for all finite horizon versions of the problem. This paper characterizes stochastically optimal policies as policies that process a similar property, i.e. they are optimal in expectation for all members of a sequence of appropriately defined finite horizon problems. The authors use this characterization to establish the stochastic optimality of relevant policies for the optimal repair allocation for a series system problem and for a scheduling problem. (Author)

ABSTRACT: (U) The goal of this program is to understand turbulence chemistry interactions in combustion up to and including localized extinction. Experimentally, pilot stabilized non premixed turbulent jet flames of selected mixtures are being studied under conditions conducive to strain-induced local extinction. Laser based techniques such as Raman scattering and Rayleigh scattering are employed. Analytically, models based on the asymptotically thin flamelet concept and on distributed reaction zone concepts are being assessed. A significant finding is that the popular contemporary view of a turbulent flame as an ensemble of asymptotically thin flamelets seems incorrect. Alternative mechanisms based on thick flamelets are proposed. The results include: (1) A complete re evaluation of Raman data showing significant corrections due to high temperature effects. Keywords: Turbulence chemistry interactions, Extinction, Blowoff, turbulent diffusion flames, Superequilibrium, Laser diagnostics.

ABSTRACT: (U) In the past year we have implemented prototypes of components of the Saguaro distributed operating system and refined the design of the entire system based on the experience. The philosophy behind Saguaro is to support the illusion of a single virtual machine while taking advantage of the concurrency and robustness that are possible in a network architecture. Within the system, these advantages are realized by the use of pools of server processes and decentralized allocation protocols. Potential concurrency and robustness are also made available to the user through low-cost mechanisms to control placement of executing commands and files, and to support semi-transparent file replication and access. Another unique aspect of Saguaro is its extensive use of type system to describe user data such as files and to specify the types of arguments to commands and procedures. This enables the system to assist in type checking and leads to a user interface in which command-specific templates are available to facilitate command invocation. A mechanism, channels, is also provided to enable users to construct applications containing general graphs of communication processes. Keywords: SR distributed programming language.

UNCLASSIFIED REPORT

ABSTRACT: (U) There are four projects underway that either have used the equipment purchased using the funds from this grant or will use the equipment in the near future. Titles and abstracts of the representative papers describing these projects follow. It is the first project the Saguaro Distributed Operating System that formed the basis for the URIP grant proposal.

ABSTRACT: (U) In this paper, we have shown that we can characterize methods for the solution of incompressible flow problems as belonging to either parabolic or elliptic type with regard to the determination of pressure field. The elliptic schemes typically have smaller errors in the divergence field, with the errors decaying exponentially away from the boundaries of the computational domain. On the other hand, the parabolic schemes have smooth solutions, without numerical boundary layers, but care should be exercised with respect to the boundary conditions in order that initial divergence errors be eliminated. This analysis explains why elliptic schemes, like that introduced by Harlow Welch (1965) have been found to be more accurate than parabolic schemes.

ABSTRACT: (U) This paper studies how sampling variation in component reliability estimates affects the computation of system reliability that uses these estimates as input. Results show that relative bias in system reliability grows quadratically with the number of components for which each component reliability estimate is used whereas the corresponding coefficient of variation grows linearly with this number of components. If these components are in parallel they lead to an understatement of system reliability. In series, they lead to an overstatement. The paper describes resampling schemes that eliminate bias without increasing the dominant variance term. (Keywords: operations research; systems analysis; statistical accuracy).

UNCLASSIFIED REPORT

ABSTRACT: (U) A fifteen-month multi-task research project was pursued by the present investigators to study complex viscous flows under AFOSR sponsorship between July 1985 and September 1986. The major objective of this study was to require improved understanding of viscous flows and to develop basic computational methods for efficient determination of 2-D/3-D subsonic and incompressible flows. Two major analyses were pursued. These include the Interacting Parabolized Navier-Stokes (IPNS) analysis for steady flows and the full Navier-Stokes (NS) analysis for direct simulation of unsteady flows. The IPNS analysis developed employs no ad hoc artificial dissipation and, in spite of being a density-based formulation, performs well even for very low Mach numbers. The applications considered include 2-D cascades and channels of simple geometry. Keywords: Viscous Flows, Flow separation, Unsteady flows, Interacting equations, Multi Block structured grids, Three dimensional flows.

UNCLASSIFIED REPORT

SUPPLEMENTARY NOTE: Pub. in International Conference on Numerical Methods in Fluid Dynamics (9th) New York, NY 1985.

ABSTRACT: (U) The calculation of viscous supersonic flow over circular cones at high angles of yaw has been partially carried out. The flow field was calculated as the interaction between the outer inviscid flow and an inner corical boundary layer flow. The latter was treated by the orthonormal version of the Method of Integral Relations (M.I.R.) and continued up to the cross flow separation line. This work deals with the boundary layer downstream of this separation line where the circumferential velocity component, w , is reversed. The orthonormal version of M.I.R. needs to be modified in this region to take account of a minimum point in w near the cone surface. In contrast to two dimensional flow, this can be achieved by using polynomials to represent the normal gradient of w as a function of w , and square root factors, which seriously complicate the use of orthonormal M.I.R., are not needed. The extended calculation enables us to calculate the complete flow field over yawed supersonic cones, at different Mach numbers and yaw angles, including that in the far leeward region. (Reprints).

ABSTRACT: (U) A new technique is described to continue along solution branches of parameter-dependent nonlinear boundary value problems in order to obtain accurate multigrid solutions at specified points. In particular, the implementation for a general class of second order equations in divergence form in the program PLTMG is described and analyzed. This method has proven to be very robust and efficient, as is illustrated by several examples. (Reprints)

ABSTRACT: (U) Changes in the discharge rates of monkey primary somatosensory cortical neurons were recorded during the performance of wrist flexion and extension. Neurons with activity changes that occurred early before movement onset were often found in areas 3a, 1 and 2, but rarely in area 3b. Based on timing considerations, these observations suggest that somatosensory cortical neurons receive central as well as peripheral inputs that modulate their activity and that may be related to changes in tactile threshold before movement. ABSTRACT: (U) The stability bound for the classical nonlinear Euler beam is determined in the case that its deflection is limited by an obstacle parallel to the plane of the beam. Let a clamped or simply supported beam be axially compressed by a force $P > P_{sub 0}$, where $P_{sub 0}$ denotes the critical load. So far only a linear theory has been applied to analyze the stability of the solutions in contact with the obstacle and the jumping to a different state. Utilizing a free boundary problem formulation we analytically as well as numerically answer these questions for the nonlinear beam. Keywords: Structural beam deflections; Bifurcation(Mathematics). EVJ50D

ABSTRACT: (U) The calculation of laminar boundary layer flow in two dimensions, using the Dorodnitsyn Method of Integral Relations, was successfully extended to separated regions. The extension requires incorporation of a square root term in the representation of the local shearing stress as a function of the streamwise velocity component. This limits the order of approximation that can be conveniently carried out for various flow configurations in plane flow and presents obstacles to the generalization of M.I.R. for three dimensional flow. The same difficulties arise in developing the orthonormal version of M.I.R. both for laminar and turbulent boundary layers. A recent paper treats laminar boundary layer flow in two dimensions by solving the Dorodnitsyn integral form of the equations of motion using a Finite Element Method. In the present paper this approach is extended to boundary layer flows dominated by positive pressure gradients. Free interaction couples the viscous and inviscid regions in which no iteration between these regions is required. (Reprints)

UNCLASSIFIED REPORT

ABSTRACT: (U) Turbularization of an acoustic boundary layer (Stokes Layer) on impermeable and permeable surfaces is analytically considered. The theoretical approach uses a second-order closure model of turbulence. Both an approximate, closed-form solution and a more comprehensive finite difference solution of the time dependent, parabolic, one-dimensional governing equations are obtained. For simple acoustic boundary-layers on impermeable surfaces, both the approximate solution and the numerical results for the critical acoustic Mach number required for turbulent transition are qualitatively confirmed by experiment. Calculations for acoustic boundary-layers with transpiration (injection) indicate a substantial reduction of the acoustic Mach number required for transition, up to a limiting injection velocity that is frequency dependent. The results may provide a mechanism for flow-related combustion instability in practical systems, particularly solid propellant rockets, since turbularization of the near-surface combustion zone could result at relatively low acoustic Mach numbers. This report documents a completed phase of work which is concerned with the

ABSTRACT: (U) A remarkably simple, experimentally
inspired, new theory of vision is presented. The theory
takes into account the parallel architecture, the
adaptive phenomena and the efferent control system which
have been demonstrated in the vision systems of organisms.
Further the complexities of visual receptive fields are
made use of to explain the speed, noise resistance,
consistencies and holistic aspects of perception. In this
theory image understanding is achieved by image seeking
adaptive networks that differentially amplify images of
interest without first breaking them down into elementary
components. A computer implementation of the theory
demonstrates that the mechanisms postulated are feasible.
A number of experiments with the model address critical
aspects of image understanding and demonstrate that
images of interest are captured reliably even in large
amounts of noise, or in spite of position and/or size
changes. Subjective edges, and other Gestalt like images,
i.e. horizon and terrain are also seen by ISAN's basic
network. Some implications for general vision are
outlined.

UNCLASSIFIED REPORT

ABSTRACT: (U) The interaction of a high speed (10-20 km/sec) plasma flow of modest temperature (0.5-5 eV) with a solid surface is a basic phenomenon in a variety of high specific power devices, such as advanced high specific impulse thrusters. Study of the details of processes involved in the immediate vicinity of the surface is normally precluded by the very limited diagnostic access afforded in mission-oriented devices. The present research program establishes a plasma flow by means of a quasi-steady magnetoplasdynamic arcjet and exposes simple solid surfaces to this flow while examining the plasma surface interaction spectroscopically. Detailed measurements provide the benchmark for theoretical modeling that may then be applied to the more complex geometries of actual plasmadynamic devices. The present report covers the development and characterization of the arcjet plasma source and the initial results from experimental diagnostics focused near the surface of a dielectric blunt body in a high speed argon flow.

UNCLASSIFIED REPORT

ABSTRACT: (U) The spectral representations for arbitrary discrete parameter infinitely divisible processes as well as for (centered) continuous parameter infinitely divisible processes, which are separable in probability, are obtained. The main tools used for the proofs are (I) a polar-factorization of an arbitrary Levy measure on a separable Hilbert space, and (II) the Wiener-type stochastic integrals of non-random functions relative to arbitrary infinitely divisible noise.

SUPPLEMENTARY NOTE: Pub. in International Conference on Acoustics, Speech and Signal Processing, p395-398 1987.

ABSTRACT: (U) A new approach to stability of adaptive filters is presented. The notion of constrained-input/constrained-output (CICO) stability is introduced as a generalization of the standard notion of bounded-input/bounded-output (BIBO) stability. This new notion involves a set of constraints on the filter data (i.e., signals and parameters) that, unlike boundedness, are specific to the filter in consideration. The set of all data that satisfy the constraints is the feasibility domain of the adaptive filter. Three particular adaptive lattice filters are analyzed: (i) Burg's lattice, (ii) the unnormalized RLS lattice, and (iii) the normalized RLS lattice. We derive the feasibility domains of these adaptive filters and prove that they are CICO stable.

ABSTRACT: (U) The research objective of this project is to study the estimation and control of elastic systems composed of beams and plates in order to develop efficient and accurate control and estimation algorithms. In the case of estimation basic to this goal is the development of an understanding of properties of the parameter to state mapping, an approximation theory associated with the particular models and minimization problems, and the suitability of different minimization algorithms for efficient codes for various problems. In control of prime importance is to determine properties of optimal controls and feedback, best location based on design of the actuators and the geometry and elastic properties of the body, and suitable algorithms and codes for control. Toward these objectives the work during the past year has centered primarily on the estimation and control of both static and dynamic linear models.

ABSTRACT: (U) The precision of smooth pursuit eye
movements was described by means of a new dependent
measure, the 'oculomotor difference threshold' which
represents the smallest difference in target velocity
that produces statistically distinguishable differences
in eye velocity. Oculomotor difference thresholds for
constant velocity motions were largest during the initial
200 msec of target motion, despite fairly high average
gains during the same period. Oculomotor difference
thresholds declined over time. By about 600-700 msec
after the onset of target motion they reached values a
low as the perceptual difference thresholds measured
psychophysically with the same target velocities.
Nonsensory influences on smooth eye movement were also
found. Keywords: Eye movements; Smooth pursuit; Velocity
discrimination; Weber fraction; Difference threshold;
Reprints.

UNCLASSIFIED REPORT

SUPPLEMENTARY NOTE: Pub. in AIAA Jnl., v25 n3 p401-407
Mar 87. Presented at AIAA Aerospace Sciences Meeting
(24th), Reno, NV, 6-9 Jan 86.

ABSTRACT: (U) A comparative study is made between the
MacCormack explicit-implicit predictor-corrector and the
Beam-Warming fully implicit algorithms for solving
compressible viscous flow. The mass-averaged, two-
dimensional compressible Navier-Stokes equations in
strong conservation law form and general curvilinear
coordinates are solved numerically by marching forth in
time on a body-fitted curvilinear grid for a shock-wave/
turbulent boundary-layer interaction over a two-
dimensional compression corner. Computations are
performed for a Mach number of 1.96 with a Reynolds
number Resub delta sub infinity (based on the incoming-
layer thickness delta sub infinity of 250,000 and for a
Mach number of 2.83 with a Reynolds number of 1,800,000.
The primary objectives of the study are 1) to determine
the extent to which the steady-state solution obtained by
the hybrid MacCormack algorithm is dependent upon the
size of the time step employed in marching the
calculation toward the steady-state solution, 2) to
compare the two algorithms regarding accuracy and
efficiency, and 3) to further examine the efficiency, and
3) to further examine the efficacy of the Baldwin-Lomax
algebraic turbulent eddy-viscosity model through
comparison with recent experimental measurements of the
Reynolds shear stress. (Author)

ABSTRACT: (U) Silicon Hydride has been identified as a
photolysis product in the infrared multiple photon
dissociation of RSiH₃ (R = n-butyl, phenyl), arising from
secondary IR MPD of silane produced in the initial four-
center elimination step. The radiative lifetimes of
levels show a strong rotational state dependence. The
infrared multiple photon dissociation (IR MPD) of
organosilanes has been observed to yield olefins, silane,
and a deposit of adjacent surfaces identified as
amorphous silicon (a:Si-H). The low silane olefin product
ratios found in those experiments, and the accompanying
deposition of a:Si-H, were attributed to secondary IR MPD
of the vibrationally hot silane produced in the initial
photolysis steps to yield silylene (SiH₂). In order to
verify this proposed mechanism, we have used laser
excited fluorescence (LIF) to detect the SiH₂ produced in
this reaction.

ABSTRACT: (U) The first silanediimine, N,N'-bis(trimethylsilyl) (Me₃SiN=Si=NSiMe₃) (5) has been photochemically generated from 2,2-diazidohexamethyltrisilane (1) in hydro-carbon glasses at low temperatures. Photolysis of 1 at 254 nm leads first to the azido-silanimine Me₃SiSi (N₃)=NSiMe₃, lambda max 274 nm, which undergoes further photolysis to produce 5. The silanediimine has an absorption maximum at 324 nm (epsilon = 2130 + or - 260 M/cm) and reacts with Me₃SiOMe to give ((Me₃Si)2N)2Si(OMe)2.

ABSTRACT: (U) Orbital alignment effects are investigated for an energy transfer process involving several competing pathways in the system Sr (5s6p1p1) + rare gases and H₂. Most of the cross sections to populate either (1) the combined 5s6p 3pJ and 4d5p 3f4 states or (2) the individual 4d5p 3f3 level show a marked preference for the perpendicular approach of the p orbital. However the cross section with He to populate the 3f3 state strongly favors the parallel orbital direction. Keywords: Alignment, Electronic energy transfer, Laser, Orbital effects, Strontium, Hydrogen.

SUPPLEMENTARY NOTE: Pub. in Jnl. of Molecular Structure,
v147 p363-368 1987.

ABSTRACT: (U) The geometric structure of C-C4F8SF4 has been determined by gas-phase electron diffraction. The five-membered ring has the twist form (C2 symmetry) with a puckering amplitude $q = 0.42$ (2). The following principle geometric parameters (in Å) with estimated uncertainties have been derived: (C-C)av = 1.541 (10), S-C = 1.896 (7), S-Fe = 1.558 (6), S-Fe = 1.594 (6) Å, CSC = 90.0 (9), SCC = 109.1 (8), CCC = 106.5 (12), FCSFe = 90.5 (15) and FeSe = 87.7 (29). Vibrational amplitudes for long non-bonded C...F and F...F distances indicate a high barrier to pseudorotation of the ring. Keywords: Gas phase electron diffraction, Conformational, Dynamic properties, Five membered rings, Rigid structure, High pseudorotation barrier.

ABSTRACT: (U) The authors consider various physical problems which may be formulated in terms of integral equations of the first kind, including the two-dimensional screen Neumann and Dirichlet problems in acoustics (and crack problems in elasticity). Sharp regularity results for the solutions are available for these problems. Proven is the convergence of the p-version for some Galerkin boundary element schemes based on the integral equation formulations. It is shown that the rate of convergence obtained by our method is twice that for the usual h-version.

UNCLASSIFIED REPORT

ABSTRACT: (U) A lot of work has been done towards the direction of developing communication protocols that determine how a single common resource can be efficiently shared by a large population of users. By now, it is well known that fixed assignment techniques are not appropriate for a system with large population of bursty users. In the latter case, random access protocols are more efficient and many of them have been suggested. Usually, the amount of information transmitted per time is of fixed length, called a packet. In most of the systems, time is divided into slots of length equal to the time needed for a packet transmission (slotted systems). The deployment of an ever increasing number of multi-user random access communication networks. Brought up the question of how packets whose destination is another network, should be handled. Thus, the issue of network interconnection or multi-hop packet transmission, arises, 3, 6, 7. The basic problem in analyzing interconnected systems is that of characterizing the output process of a multi-user random access communication system; i.e., the departure process of the successfully transmitted packets.

ABSTRACT: (U) Contents: Finite Element Methods for the Ladyzhenskaya Model of Viscous Flow; Survey of Finite Element Methods for Incompressible Viscous Flows; Finite Element Methods for Hyperbolic Equations.

ABSTRACT: (U) Experimental measurements have been made and interpreted in acetylene/oxygen and benzene/oxygen/argon flames at 2.7 kPa, and an unburned flow velocity of 50 cm/s with the objective of evaluating the ionic mechanism of soot nucleation. This mechanism postulates that chemi-ions are precursors of soot and that the initial reactions in the soot and nucleation process are ion-molecule reactions in which molecular ions continually increase in size until they are neutralized by ion combination. Total ion profiles were determined by Langmuir probe; individual ion profiles were determined by Langmuir probe; individual ion profiles were determined by molecular ion sampling mass spectrometry up to about mass 600; temperature profiles were determined by radiation corrected thermocouples. It is demonstrated that the ion concentration is greater than the concentration of soot particles; and ions decay as soot is produced. In the acetylene/oxygen, the ion-molecule reaction rates are measured and compared with other measured and calculated rates. It is demonstrated that these rates are rapid at flame temperatures. Some major differences were found in the features of benzene and acetylene ion profiles that remain to be explained. The experiments are strongly supportive of the ion mechanism of soot formation in flames.

ABSTRACT: (U) This research project is investigating strategies to pharmacologically manipulate the circadian sleep-wake cycle in order to control the timing of alert function and of sleep in altered work schedule environments. In the past year we have investigated the benzodiazepines, diazepam (in hamsters) and triazolam (in squirrel monkeys), and have derived a phase response curve for each. In optically-enucleated hamsters, however, consistent phase shifts were not obtained suggesting that diazepam acts on light information-conveying pathways. Biochemical receptor binding studies are defining the benzodiazepine receptor density in various brain regions. In addition, the characterization of the circadian and homeostatic components of sleep in the squirrel monkey during sleep deprivation studies is being conducted in preparation for pharmacological manipulation with benzodiazepines. ABSTRACT: (U) This report describes the progress made during the first year of an equipment grant which has provided a common computing environment for four laboratories conducting research in perception and cognition at the University of Minnesota. Research in the Cognitive Psychology Laboratory has shown that learning a procedural skill can occur in the absence of any declarative learning. Progress has also been made toward developing a computer simulation of this process. In the Visual Psychophysics Laboratory several image-enhancement algorithms have been developed as well as a psychophysical procedure for evaluating those algorithms. Research in the Auditory Psychophysics Laboratory has concentrated on developing a model of the detection and recognition of complex auditory signals by human observers. A subset of the model has been implemented as a computer simulation and several experiments have been completed to guide its future direction. In the Psycholinguistics Laboratory a computer model of text comprehension and recall has been constructed. Several experiments have been completed that confirm assumptions built into the model and show a good correspondence between its performance and that of human subjects.

ABSTRACT: (U) This paper considers the linear quadratic optimal control problem on infinite time interval for linear time-invariant systems define on Hilbert spaces. The optimal control is given by a feedback form in terms of solution p_i to the associated algebraic Riccati equation (ARE). A Ritz type approximation is used to obtain a sequence p_i sub n of finite dimensional approximations of the solution to ARE. A sufficient condition that shows N sub n converges strongly to p_i is obtained. Under this condition, we derive a formula which can be used to obtain rate of convergence of N sub n to p_i . We demonstrate and apply the results for the Galerkin approximation for parabolic systems and the averaging approximation for heredity differential systems. (Author)

ABSTRACT: (U) Several lattice forms and algorithms which constitute the immittance domain alternatives to the PARCOR lattice algorithm are presented. The immittance variables were shown to offer more efficient Levinson algorithms than the conventional scattering algorithms for both symmetric and Hermitian Toeplitz matrices. This paper presents the lattices associated with the new recursions and provides algorithms to determine their coefficients directly from the signal segments. The new lattices are of interest for speech processing as they offer a different parametrization and process real signal segments with only one multiplier and two adders per section. Complex signal segments require two adders per section. Stability conditions for the new parametrizations are also presented.

ABSTRACT: (U) The treatment of separation of laminar and turbulent boundary layers using an inviscid-viscous flow matching approach is reviewed. In two dimensions this approach has been thoroughly investigated and a number of numerical techniques have been tested successfully against experimental results. The approach was initiated in a series of pioneer papers (Crocco and Lees, J. Aero. Sci., 1952, Lees and Reeves, AIAA J., 1964, Catherall and Mangler, J. Fluid Mech., 1966) in which the original Prandtl boundary layer concept was modified. Traditionally, in airfoil calculations, for example, the value of the pressure appearing in the boundary layer equations was calculated from an inviscid flow calculation past the airfoil profile. In the modified approach the inviscid calculation is to be applied to a profile displaced outwards through a distance equal to the boundary layer displacement thickness.

ABSTRACT: (U) The computation of system reliability from component reliabilities presents a host of non-trivial problems for systems of varying sizes. These include the functional relationship between the time required to compute system reliability and system size. A second problem concerns how system reliability varies as component reliabilities vary. A third problem concerns how statistical errors in estimating component reliabilities affect the accuracy of the system reliability computation. This paper describes Monte Carlo techniques which provide useful answers to the first two problems and presents an analysis which establishes the potential seriousness of the third problem in practice.

ABSTRACT: (U) Based on randomly right-censored data, a smooth nonparametric estimator of the quantile function of the lifetime distribution is studied. The estimator is defined to be the solution $x_{sub n}(p)$ to $F_{sub n}(p) = 0$, where $F_{sub n}$ is the distribution function corresponding to a kernel estimator of the lifetime density. The strong consistency and asymptotic normality of $x_{sub n}(p)$ are shown. Some simulation results comparing this estimator with the product of the bandwidth required for computing $F_{sub n}$ is investigated using bootstrap methods. Illustrative examples are given. ABSTRACT: (U) In solids with a coupling between guest
and host atoms, a new mechanism of cooperative
transitions is possible since the centers formed by the
guest atoms involve surrounding host atoms. This leads to
orbital overlap between centers via the host atoms which
can result in cooperative transitions. The cooperative
transition moments are estimated for rare gas solids
doped by halogens. Keywords: Cooperative optical
transitions, Orbital overlap via host atoms, impurity
centers, solids, rare gas solids, doped with halogens.

ABSTRACT: (U) Frequently bifurcations in nonlinear
eigenvalue problems are due to symmetries in the problem.
At bifurcation points the symmetries in the solution are
typically reduced on the bifurcating branches. We present
an algorithm that by making explicit use of the symmetry
behavior of the solutions allows us to determine these in
a reliable and efficient way. Numerical results are
presented for a finite-difference discretization of a
Duffing equation with periodic boundary conditions.

ABSTRACT: (U) We advance a coherent development of zero-crossing-based methods and theory appropriate for fast signal analysis. Quite a few ideas pertaining to zero-crossing counts found in the literature can be expressed and interpreted with the help of this more general setup. A central issue addressed in some detail is the fruitful connection which exists between zero-crossing counts and linear filtering. This connection is explored and interpreted with the help of a certain zero-crossing spectral representation, and is then applied in spectral analysis, detection, and discrimination. Zero-crossing counts in filtered time series are called higher order crossings. The theme of this work is that higher order crossings analysis provides a useful descriptive as well as an analytical tool that can in many respects match spectral analysis. To a great extent these two types of analysis are, in fact, equivalent, but each emphasizes a different point of view. Advantages offered by higher order crossings are great simplicity and a drastic data reduction. (Reprints)

ABSTRACT: (U) The measurements of the angular distribution of desorbing positive ions produced by electron impact desorption (ESDIAD) is of fundamental importance in understanding molecular structure in the chemisorbed layer. In this short review, two applications of ESDIAD to structural problems in the adsorbed layer will be described. Examples of strong chemisorption and weaker physical adsorption effects will be discussed. In addition, interactions between adsorbed species, leading to changes in bonding geometry will be described. The apparatus used for this work allows digitized acquisition of ion angular distributions in the absence of background effects due to soft X ray emission stimulated by electron impact. Keyword: Chemisorption physisorption, Stepped surfaces, Cyclopentene, Surface electric field, Silver nickel.

Polymers, p106-116 1987.

ABSTRACT: (U) This paper presents studies of solid state polymerization aimed towards formulating a dynamic model of reactivity in the condensed phase. Phonon spectroscopy is successfully used to elucidate the mechanism of lattice control of the reaction. Novel concepts of phonon-assisted thermal and photochemical reactions are introduced, supported by experimental data. Non-linear laser spectroscopy is used to find the importance of biexcitonic processes in photopolymerization. Also, spectroscopic studies of reactions in Langmuir Blodgett films and at gas solid interface which produce ordered polymers are presented.

ABSTRACT: (U) Experiments have been carried out in a variable pressure flow facility with the objective of studying the structure of a co-flowing jet diffusion flame. The flow is visualized using an optical scheme which superimposes the luminous image of the flame on its Schlieren image. This gives a useful picture of the relationship between the bright, yellow-orange, soot-laden core flow and the edge of the surrounding hot gas envelope. A loudspeaker is used to force the central fuel jet at several frequencies. In the unforced flow and over most of the driving frequency range in the forced flow, a double structure is observed with two distinct wavelengths: a long wavelength associated with the luminous, buoyancy-driven core flow and a short wavelength associated with the shear-driven outer flow. Excitation at the proper frequency causes strong coupling to occur. In this case the core flow pinches off and the flame breaks up into a series of flamelets moving with a single wavelength.

p1475-1479, 15 Jul 87.

ABSTRACT: (U) The lifetimes of molecules located close to a sinusoidal grating surface are studied within a classical phenomenological model. The contribution of surface roughness to the molecular decay rate is attributed to the discrepancy between the experiments of Rossetti and Brus and the theory of Chance, Prock, and Sibley. It is found that surface roughness can either enhance or diminish the flat-surface value for the decay rate depending on the emitting frequency, molecule-surface distance and the molecular orientation. Keywords: Molecular lifetimes; Metallic surfaces; Periodically roughened; Molecule surface distance; Molecular orientation; Classical model.

ABSTRACT: (U) This paper is concerned with periodic, laser-induced, chemical vapor deposition recently observed experimentally. In order to inquire further into this phenomenon, it is first necessary to find a simple means of calculating the plasmon field strength for relatively deep gratings. The Rayleigh hypothesis is assumed, and only p-polarized, normally incident light is considered. A closed-form equation for the plasmon field intensity is then derived. Also discussed is the behavior of the plasmon dispersion relation for a shallow grating, but for a complex dielectric constant where the imaginary part is not necessarily small. Keywords: Plasmons; Chemical vapor deposition; P-polarized light; Complex dielectric constant. (Reprints)

ABSTRACT: (U) The physical phenomena described by nonlinear partial differential equations have become at present the central theme of investigations by many researchers. A good understanding of most physical processes requires accounting for nonlinear effects and, consequently, methods for studying nonlinear equations have to be developed. Among nonlinear equations the Dirichlet problem for the Monge-Ampere equation is the model case for fully nonlinear equations.

ABSTRACT: (U) The probability of error in a binary
 symmetric channel with intersymbol interference and
 additive noise is efficiently calculated by numerical
 quadrature of a Laplace inversion integral along a
 contour in the complex plane passing through a
 saddlepoint of the integrand. For Gaussian noise a bound
 is set on the truncation error incurred by necessarily
 restricting the integration to a finite interval. The
 probability of error resulting from cochanel
 interference is calculated by a similar technique.

ABSTRACT: (U) Matching data from a bivariate population
 is considered when observations are available only in the
 form of a broken random sample. In other words, a random
 sample of n pairs is drawn from the population but the
 observed data consist of n observations on the second
 component and the n observations on an unknown
 permutation of the first component of the n pairs of data.
 A maximum likelihood matching strategy is revisited. The
 proportion of approximately correct matches (due to Yahav)
 is used to evaluate the performance of the pairing
 strategy as n approaches limit of infinity. The small
 sample behavior of this proportion is studied via a Monte-
 Carlo simulation in the special case of bivariate normal
 parent population. Keywords: Asymptotic properties;
 Statistical data; Tables(data).

ABSTRACT: (U) This document describes Hilbert Space Valued Random Variables. Keywords: Banach space: Orthogonality arrays.

ABSTRACT: (U) The principle objective of this study is to identify and develop an understanding of the mechanisms whereby acoustic suppressants modify an acoustic wave. The experimental bases for the technical approach of this study is a Rijke burner which generates combustion oscillations. During the past year three major modifications were made to the Rijke burner to facilitate obtaining more reproducible data: (1) The cooling jacket was rebuilt to give better heat transfer characteristics, and a flowmeter was incorporated to allow a quantitative control of the cooling water flow. (2) A digital data acquisition system was interfaced with the burner to allow monitoring more variables, and to improve data reduction techniques. (3) A new damping device consisting of a butterfly valve and a sound absorbing cone below the burner was developed to allow greater damping. Acoustic growth rate data have been obtained a nominal frequency of 1200 Hz varying the mass flow rate, the oxidizer/fuel ratio, and the relative amount of nitrogen. In all cases, the growth rate increases as the energy release rate (or temperature) increases. These data will now be compared to the previously developed model to better understand the physical mechanisms driving the acoustic oscillations. The model is also being modified to incorporate various submodels for different types of particulates. Keywords:

ABSTRACT: (U) The objective of the work carried out under this grant was to perform physical electrochemical and electroanalytical studies at various kinds of solid electrodes. The physical electrochemical investigations were divided into studies of heterogeneous electrode kinetics, underpotential deposition and electrocatalysis. The electroanalytical work areas involved trace analysis of solutions using hydrodynamic voltammetry and of solutions and gases using porous electrode structures. Novel porous electrode techniques were developed for the analysis of trace species present in both liquid and gas phases. Two novel and simple electronic circuits were developed for electrochemical applications.

ABSTRACT: (U) This report describe procurements made under contract number AFOSR-85-0120, as part of the Department of Defense, University Research Instrumentation Program. The equipment purchased is in support of analysis and encoding of color motion imagery. Installation of all equipment has been completed and is functional, attached to a VAX 11/750 in the Department of Electrical Engineering and the Center for Computer Aided Engineering. The major expenditure was for a Gould IP8400 imaging system with high-speed (30 frames per second) color storage and display. This system is operated as a peripheral on the VAX 11/750 running UNIX. To support image processing tasks, a CDA Array Processor was also purchased and attached to the system bus. Finally, to aid in data presentation, a hard-copy print camera was purchased from NISE Corp. The equipment is presently being used for a variety of image processing tasks, both for still and moving images. Plans include doing computer vision research and interdisciplinary work with groups who need real-time display of imagery.

ABSTRACT: (U) This paper presents results on the
convergence and asymptotic agreement of a class of
asynchronous stochastic distributed algorithms which are
in general time-varying, memory-dependent, and not
necessarily associated with the optimization of a common
cost functional. It is shown that convergence and
agreement can be reached by distributed learning and
computation under a number of conditions, in which case a
separation of fast and slow parts of the algorithm is
possible, leading to a separation of the estimation part
from the main algorithms.

ABSTRACT: (U) Consider a class of suspensions of diffeomorphisms of the annulus as flows in the orientable 3-manifold $T^2 \times I$. Construct a knotoid or template that carries the set of periodic orbits of the flow. We define rotation numbers and show that any orbit of period q and rotation number p/q can be arranged as a positive braid on p strands. This yields existence and uniqueness results for families of resonant torus knots (p-braids that are (p,q) -torus knots of period $q > p$), which correspond to order-preserving (Birkhoff-) periodic orbits of the diffeomorphism. Show that all other q -periodic p-braids have higher genus, and establish bounds on the genera of such knots. Obtain existence and uniqueness results for a number of other, non-resonant, torus knots, including non-order-preserving $(q + s, q)$ -torus knots of rotation number 1. (Reprints)

SUPPLEMENTARY NOTE: Pub. in Physica, v24D p383-390 1987.

ABSTRACT: (U) Experimental evidence is presented which supports the theory that homoclinic orbits in a Poincare map associated with a phase space flow are precursors of chaotic motion. A permanent magnet rotor in crossed steady and time-varying magnetic fields is shown to satisfy a set of third order differential equations analogous to the forced pendulum or to a particle in a combined periodic and traveling wave force field. Critical values of magnetic torque and forcing frequency are measured for chaotic oscillations of the rotor and are found to be consistent with a lower bound for the existence of homoclinic orbits derived by the method of Melnikov. The fractal nature of the strange attractor is revealed by a Poincare map triggered by the angular position of the rotor. Numerical simulations using the model also agree well with both theoretical and experimental criteria for chaos.

UNCLASSIFIED REPORT

ABSTRACT: (U) Work continues primarily in gas phase
turbulent mixing and chemical reactions with extensions
to compressible (supersonic) shear layers. In the gas
phase shear layer work, investigations concentrate on
subsonic shear layer free stream density ratio effects,
and a design effort in support of the planned extension
of the hydrogen-fluorine shear flow facility to
supersonic flows. In jet flows, measurements of gas phase
jet mixing, using laser Rayleigh scattering techniques
developed for conserved scalar measurements down to
diffusion space and time scales, are in progress. A first
publication has just appeared on an experiment in which
digital imaging of soot in turbulent flames was used to
describe combustion flame sheets in methane flames.
Analytical/computational modeling efforts included
development of quantitative description of turbulent jet
mixing and chemical reactions including finite Damkoehler
number effects; supersonic shear layer combustion studies
of finite kinetic rate (Damkoehler number) effects for H₂/
F₂/NO and H₂/air systems; a new analytical model for
turbulent shear layer mixing and chemical reactions; and
extensions of hydrodynamic stability calculations to
include Mach number effects in supersonic shear layers.

DESCRIPTORS: (U) *CHEMICAL REACTIONS, *MIXING.

UNCLASSIFIED REPORT

ABSTRACT: (U) Wave propagation characteristics of large space structures (LSS) affect their performance, integrity and the ability to nondestructively assess their integrity. In this study, wave propagation characteristics of an aluminum 22-bay planar lattice structure are determined experimentally. Two ultrasonic piezoceramic longitudinal transducers are mounted at various locations on the structure. Wave measurements are obtained by injecting an impulsive load via the transmitting transducer and recording the response via the receiving transducer. The waves injected into the structure are longitudinal waves, transverse to the surface, although a complex stress distribution which may be described by directivity functions is actually realized. The impulsive loading signal has a broad frequency spectrum containing frequencies greater than 0.5MHz.

SUPPLEMENTARY NOTE: Pub. in Proceedings of the American
Control Conference, p502-505 1987.

ABSTRACT: (U) The axis-crossing counts in time series
and in its successive differences are called higher-order
crossings (HOC). Under the Gaussian assumption the
sequence of expected HOC is monotone increasing and
admits a spectral representation which establishes a
clear connection between HOC and the spectrum. In
particular the normalized number of axis-crossings (first
HOC) tend to admit values at or near a dominant frequency
in the spectrum. When the series is first lowpass
filtered, the resulting normalized HOC tend to 'visit'
true discrete frequencies on their way to the highest
frequency. If the successive differences are replaced by
successive summation, the resulting modified normalized
HOC converge monotonically to the lowest frequency in the
spectrum. Keywords: Dominant frequency; Highest frequency;
Spectral; Gaussian; Monotone sequence; Mathematical
filters; Reprints.

ABSTRACT: (U) While bifurcation theory has developed rapidly in recent years, there appears to be a need for a tighter framework for the numerical analysis of bifurcation problems. This paper presents such a mathematical framework for the numerical study of the bifurcation phenomena associated with a parameter-dependent equation $F(z, \lambda) = 0$. The presentation draws from differential geometry and singularity theory and provides a basis for various numerical methods used to detect and compute certain types of bifurcation points. Keywords: Reprints; Differentiable manifolds; Singular points; Numerical bifurcation; Augmented equations.

ABSTRACT: (U) In this paper it is shown how a block cyclic successive overrelaxation direct-iterative method can be applied to the parallel solution of certain large-scale linear equality-constrained quadratic programming problems. The scheme is similar in nature to those studied recently by de Pillis, Niethammer and Varga and by Markham, Neumann and Plemmons for solving large sparse least squares problems. It is based upon a partitioning strategy of the fundamental matrix into a block consistently ordered 2-cyclic form where the nonzero and eigenvalues of the Jacobi matrix are all pure imaginary. The method is shown to be globally convergent and convergence rates are established. Applications of the algorithms are discussed for large-scale structural analysis computations where it is shown how the algorithm can be adapted to the simultaneous computation of the system forces and the nodal displacements. Here, advantage can be taken of the special forms of the matrix involved. In particular, it is shown that much of the algorithm lends itself to efficient implementation of pipelined vector machines and on multiprocessors. (Author)

SUPPLEMENTARY NOTE: Revision of report dated 10 Dec 86.

ABSTRACT: (U) It is shown that any form of Search Rearrangement Backtracking (SRB) requires exponential time to verify the unsatisfiability of nearly all of a wide class of CNF boolean expressions. This result is based on an input model which generates r independent k -literal clauses from set of r boolean variables. We assume that k is fixed and n and r tend to infinity. The result holds if the limit as n approaches infinity of $n/r(n) = \lambda$, is fixed and $\lambda > \ln(2)/(1-2)$ to the $-K$ power). SRB requires superpolynomial time nearly always if λ is replaced by $\lambda(n) = o(n)$ to the $1/\ln n$ power and the limit as n approaches infinity of $\lambda(n) = \infty$ (so the superpolynomial time result holds, for example if $\lambda(n) = (\ln(n))$ to the beta power, where beta is any positive constant) These results apply to any form of the Davis-Putnam Procedure.

UNCLASSIFIED REPORT

ABSTRACT: (U) An experiment was performed to examine the unsteady aerodynamics of stall penetration at constant pitch rate and high Reynolds number, in an attempt to more accurately model conditions during aircraft post-stall maneuvers and during helicopter high speed forward flight. The model spanned the 8 ft wind tunnel and consisted of a 17.3 in. chord wing with a Sikorsky SSC-A00 airfoil section. Two forms of pitching motion were used: constant pitch rate ramps and sinusoidal oscillations. Ramp data were obtained for 36 test points at pitch rates between 0.001 and 0.020. Mach numbers between 0.2 and 0.4, and Reynolds numbers between 2 and 4 million. Sinusoidal data were obtained for an additional 9 conditions. The results demonstrate the influence of the leading edge stall vortex on the unsteady aerodynamic response during and after stall. The vortex-related unsteady increments to the lift, drag, and pitching moment increase with pitch rate; the maximum delta C sub L is 1.2 at A = 0.02. Angular delays in stall events also increase with pitch rate. Vortex strength and propagation velocity were determined from pressures induced on the airfoil surface. The vortex is strengthened by increasing the pitch rate, and is weakened both by increasing the Mach number and by starting the motion close to the

ABSTRACT: (U) The present authors have studied the scattering of electromagnetic waves using variational method. Thus, that the work can be regarded as an extension of the work Tai and Cassedy and Fainberg to include both finite conductivity and arbitrary angle of incidence. Differential scattering patterns are then computed, along with the scattering, absorption and extinction. These cross sections are obtained by integrating the normal component of the Poynting vector over the surface of the fiber, enabling us to avoid the integration over the far-field sphere usually employed to compute scattering. In addition, it is found that energy considerations are exactly satisfied: the extinction cross section, which by the optical theorem must equal the imaginary part of the forward amplitude, is identically equal to the sum of the absorption and scattering cross sections. This result is particularly valuable for those applications in which we study the scattering and absorption properties of the cloud of such fiber particles.

ABSTRACT: (U) This book contains most of the papers
presented at the symposium: Materials for Infrared
Detectors and Sources held in Boston, Massachusetts,
December 1-5, 1986. This symposium brought together the
leading groups from the USA, Europe and Japan working on
the preparation and characterization of materials for
infrared detectors and sources. Much of the activity in
this field is driven by the need for focal-plane array
imagers operating in the medium (3-5 micron) and long (8-
14 micron) wavelength atmospheric transmission windows.
In addition there is now a growing interest in the
preparation and exploration of detector and source
materials for fiber-optic communications at wavelengths
beyond 1.5 microns. The objectives of the symposium were
threefold: firstly, to review progress in the key areas
of bulk and epitaxial growth technologies for preparation
of infrared materials; secondly, to review techniques for
characterization of infrared materials; and thirdly, to
evaluate the potential of novel materials and structures

ABSTRACT: (U) In this paper, we propose a modified Capon beamformer to give improved performance in coherent jamming environments. First, we briefly discuss the interference rejection and signal cancellation properties of the Capon beamformer in the presence of correlated interference, with a view to motivating the need to decorrelate the desired source signal from the interferences. We then introduce subarray covariance averaging techniques for decorrelating the impinging sources, and present an optimal weighting scheme that ensures perfect decorrelation of the sources for any given number of subarrays. Computer simulations are included to support our analysis.

ABSTRACT: (U) A parallel algorithm is developed for Cholesky factorization on a shared-memory multiprocessor. The algorithm is based on self-scheduling of a pool of tasks. The subtasks in several variants of the basic elimination algorithm are analyzed for potential concurrency in terms of precedence relations, work profiles, and processor utilization. This analysis is supported by simulation results. The most promising variant, which we call column-Cholesky, is identified and implemented for the Denelcor HEP multiprocessor. Experimental results are given for this machine. Keywords: Reprints; Charts; Statistical data; Self-scheduling loops; Experimental data. (Author)

ABSTRACT: (U) A loglinear model for predicting magazine exposure distributions is developed and its parameters are estimated by using the maximum likelihood technique. The accuracy of the loglinear and a Dirichlet-multinomial model are compared using 1985 AGB McNair data. The result shows that the loglinear model has significantly smaller prediction errors than the Dirichlet-multinomial model. A simple algorithm for optimal media scheduling is given. ABSTRACT: (U) The Bayesian nonparametric approach to estimating the tolerance distribution in quantal bioassay has received some attention. The computational difficulty in evaluating these Bayes estimators has hindered their applications. This paper explores the linear Bayes approach to the bioassay problem. These linear Bayes estimators can be computed easily by using statistical software which has the capability of inverting a matrix. Let us state the quantal bioassay problem as follows: The experimenter intends to test the potency of a stimulus by giving subjects injections of the stimulus at different levels; namely, he chooses L dosage levels, t sub $1, \dots, t$ sub L , and treats n sub $1, \dots, n$ sub L subjects at these levels respectively. Each subject possesses a fixed tolerance level. If a stimulus exceeds a subject's tolerance level, the subject responds positively. If not, there is no response. Therefore we observe the number of positive responses at each level. These numbers are denoted by k sub $1, \dots, k$ sub L . The potency curve F is the distribution of tolerance levels; i.e. F is defined by the probability $F(t)$ of getting a positive response to a dosage at level t for all t . The objective of this article is to make inferences about the potency curve F . Keywords: Ferguson's Dirichlet process.

ABSTRACT: (U) A multi user random access communication system with a population of two classes of users is considered. It is assumed that packets generated by users from different classes have different priorities. Fast moving users in a mobile communication system, or high priority users in a static environment, might be members of the high priority class. A binary feedback collision resolution algorithm is developed and both throughput and delay analysis are performed. Analytical results show that for the operation region of practical interest, the high priority class experiences significantly shorter delays, compared to the low priority one which maintains good delay characteristics. UNCLASSIFIED REPORT

ABSTRACT: (U) This paper develops an algebraic approach to the multiple time scale analysis of perturbed linear systems based on the examination of the Smith form of the system matrix viewed as a matrix over a ring of functions in the perturbation parameter. This perspective allows us to obtain a strengthened version of the results of an earlier work and to provide a bridge between these complex but general results and previous explicit, conceptually simple, but somewhat restrictive results. In addition, the authors' algebraic framework allows them to investigate a variety of other problems. In this paper they study the problem of developing valid time scale decompositions in cases in which weak damping terms discarded in the approaches in earlier works must be retained. Also, this approach exposes the role of the invariant factors of the system matrix in determining its time scales. This leads naturally to the problem of time scale modification, i.e., invariant factor placement, via state feedback. A result along these lines is presented.

ABSTRACT: (U) The exact likelihood of the data coming from a moving average model of order is complicated. In this paper, the authors propose a method of estimation of the parameters of a moving average model of order one based on the approximate likelihood of the data and on the simulation of a pair of random variables. Some comparisons were made of this method with some well known methods for moderate sample sizes. A computer program is appended which is helpful in using this methods. Keywords: Time series; Analysis; Computerized simulation; Multivariate analysis.

ABSTRACT: (U) This paper extends and generalizes to the multivariate set-up earlier investigations related to expected remaining life functions and general hazard measures including representations and stability theorems for arbitrary probability distributions in terms of these concepts. (Author)

ABSTRACT: (U) Suppose that $X_{sub 1}, \dots, X_{sub n}$ are iid. samples drawn from a d -dimensional population with density function f . Let $f(x)$ sub $n = f$ sub n sub $(x; X$ sub $1, \dots, X$ sub $n)$ be an estimator of $f(x)$. The Integrated Square Error (ISE) and Mean Integrated Square Error (MISE) of f sub n are important and widely used criteria in evaluating the performance of an estimator f sub n . Quite a lot of works appeared in the statistical literature dealing with the asymptotic properties of them, for various types of estimators, such as kernel estimator, orthogonal series estimator, nearest neighbor estimator, etc. This paper the authors describe the necessary and sufficient conditions for the histogram estimator.

UNCLASSIFIED REPORT

ABSTRACT: (U) Linear regression models are widely used in statistical analysis of experimental and observational data. Usually the linearity of the model is merely an assumption and cannot be taken for granted. In some planned experiments, repeated measurements on the dependent variable Y can be taken while the independent variable X is held fixed. In such cases standard analysis-of-variance technique can be employed to generate a test for linearity. In many applications, however, the independent variable is observed simultaneously with Y . That is to say, X , as well as Y , is a random variable. Under such circumstances the usual method for testing linearity cannot supply. This paper studies this problem in large-sample context. The authors propose a method to test the linearity hypothesis based on a grouping of the data. The critical value of test-statistic is determined so that the test has a prescribed level of significant alpha asymptotically as the sample size tends to infinity. The consistency of the test is established, and the asymptotic power is calculated when the distance (in some sense) between the true regression function and the space of linear functions tends to zero in some specific rate.

ABSTRACT: (U) In one-way random effects unbalanced model the locally best invariant test for the equality of the treatment effects is derived. Surprisingly, this is different from the widely used familiar F-test. In the balanced case, however the two tests coincide and represent the uniformly most powerful invariant tests. For two-way random effects and mixed effects balanced models, the uniformly most powerful invariant test for the equality of the treatment effects is derived both with and without interaction, and shown to be equivalent to the usual F-tests under fixed effects models. The optimum invariant tests derived here are shown not to depend on the assumption of normality. Different aspects of null, nonnull and optimality robustness of these tests (Kariya and Sinha, Annals of Statistics, 1985) are studied. In the unbalanced two-way models however unlike in the fixed effects model providing a UMPI test, both random and mixed effects models present a difficulty which is pointed out. Keywords: Multivariate analysis; Analysis of variance.

ABSTRACT: (U) In this paper, the authors investigated the rates of convergence of their estimates of frequencies and the number of signals under a signal processing model with multiple sinusoids. Keywords include: Estimation, Exponential Bounds, Frequencies, Number of Signals, Rate of Convergence, and Signal Processing.

DESCRIPTORS: (U) *CONVERGENCE, *ESTIMATES, *MODELS, *PREDICTIONS, *SIGNAL PROCESSING, FREQUENCY, LINEAR SYSTEMS, RATES, SIGNALS.

IDENTIFIERS: (U) PE61102F, WUAFOSR2304A5.

ABSTRACT: (U) The purpose of statistical analysis is 'to extract all the information from observed data'. The recorded data may have some defects such as recording errors and outliers and the first task of a statistician is to scrutinize or cross-examine the data for possible defects and understand its special features. The next step is the specification of a suitable stochastic model for the data using prior information and cross-validation techniques. On the basis of a chosen model, inferential analysis is made, which comprises of estimation of unknown parameters, tests of hypotheses, prediction of future observations and decision making. Examining data under different possible models is suggested as more informative than using robust procedures to safeguard against possible alternative models. Finally data analysis must also provide information for raising new questions and planning future investigations. Some aspects of data analysis as outlined above are illustrated through examples.

UNCLASSIFIED REPORT

ABSTRACT: (U) In many situations, we are interested in selection of important variables which are adequate for prediction under a logistic regression model. In this paper, some selection procedures based on the information theoretic criteria are proposed, and these procedures are proved to be strongly consistent. Keywords: Maximum likelihood estimation; Multivariate analysis; Asymptotic expansion.

ABSTRACT: (U) The estimation of arrival direction is an important task in signal processing and has recently received considerable attention in the literature. In this paper, the authors proposed a method to estimate the direction of arrival and proved the strong consistency of the estimates for both cases in presence of white noise and colored noise. Keywords: Algorithms; Signal processing; Multivariate analysis.

ABSTRACT: (U) In this paper, the authors consider the problem of change points using Gaussian process. The distribution of the statistic to estimate a change point constructed in this paper can be approximated by the first type of extremal distribution. Based on this, detection and interval estimation of a change point in various situations are discussed. Keywords: Variance; Heuristic methods; Asymptotic normality.

ABSTRACT: (U) For multivariate distributions with finite second order moments, a nonparametric symmetric, unbiased estimator of the generalized variance is considered, and it is shown to be (nonparametric) optimal for the class of distributions having finite fourth order moments. A jackknifed version of the sample generalized variance is also considered as a contender; it is computationally more convenient and asymptotically equivalent to the former. It is also shown that the second estimator performs quite well (in large sample) relative to the optimal normal theory estimators under several loss functions. (Keywords: kernels; U-statistics; von mises' functionals).

UNCLASSIFIED REPORT

ABSTRACT: (U) In this paper, the authors considered the problem of estimation of the frequencies and the number of signals under a signal processing model with multiple sinusoids. The frequencies are estimated with multiple eigenvariation linear prediction method. The number of signals is estimated with an information theoretic criterion. The strong consistency of the estimates of the frequencies and the number of signals is also established. Also, a modification of forward backward linear prediction method is suggested to yield consistent estimators of the frequencies.

ABSTRACT: (U) This document considers the linear regression model $y_{sub i} = x_{sub i} B + e_{sub i}$, $i = 1, 2, \dots$, where $(x_{sub i})$ is a sequence of known p-vectors, $B = (Beta_{sub 1}, \dots, Beta_{sub p})$ is an unknown p-vector, known as regression coefficients, $(e_{sub i})$ is a sequence of random errors. It is of interest to test the hypothesis $H_{sub k}$: $Beta_{sub k+1} = \dots = Beta_{sub p} = 0$, $k = 0, 1, \dots, p$. We do not assume that the random errors are identically distributed and have zero means, since it is sometimes realistic. As a compensation for this relaxation, we assume the errors have a common bounded support $A_{sub 1}$, a $Sub 2$ under certain conditions, we obtain the strongly consistent estimate of the number k for which $Beta_{sub k}$ is not equal to 0 and $Beta_{sub k+1} = \dots = Beta_{sub p} = 0$, by using the information theoretical criteria.

ABSTRACT: (U) In probability theory the following two measure theoretic problems are well known: 1) Marginal problem: for fixed probability measures (laws) P Sub 1 and P Sub 2 on a measurable space U and a measurable function c on the product space $U \times U$: $S^2 = U \times U$; and 2) Moment problem: for fixed real numbers a_{ij} and real-valued continuous functions f_{ij} ($i = 1, 2, j = 1, \dots, n$). This paper is devoted to the explicit solutions of some moment problems on separable metric space U with metric d .

ABSTRACT: (U) Two-parameter point processes are studied in connection with martingale theory and with respect to the partial-order induced by the Cartesian coordinates of the plane. Point processes are characterized by jump stopping times and by their two-parameter compensators. Properties of the doubly stochastic Poisson process, as predictability, are discussed. A definition for the Palm measure of a two-parameter stationary point process is proposed.

SUPPLEMENTARY NOTE: Prepared in cooperation with University of Regensburg, Fed. Rep. of Germany.

ABSTRACT: (U) An ill-posed linear problem $Ax=y$ in Hilbert space is considered as a filtering problem $Ax+Z=y$ for Hilbert space valued random elements. Depending on the models for the signal X and the noise Z , the solutions of this problem are discussed in the context of cylinder measures on Hilbert spaces and their regularization by the Abstract Wiener space concept. Extensions of the solutions to measurable transformations are given explicitly. The filtering solution is related to the solution of the problem $Ax=y$ obtained by Tichonov's regularization method.

ABSTRACT: (U) A short proof is given for Ito's result that the multiple Wiener integral can be written as an iterated stochastic integral, using the martingale property of Brownian motion and a simple property of symmetric tensor products of the L^2 squared - space. (Author)

SUPPLEMENTARY NOTE: Prepared in cooperation with Auburn Univ., Mathematics ACA, AL.

ABSTRACT: (U) Let $(x(t))$ be a Markov process, not assumed to be time homogeneous. It is well known that $(s(t) | \text{bar}) = (t, X(t))$ is a time homogeneous Markov process. Let A be its generator. The Feynman-Kac's formula for $x(t)$ takes the following form if the equation: $(1,1) Av + cv = 0$ admits a solution v , then v has the representation, for $s < t$: $(1,2) v(s, X_s) = E v(t, X_t) \exp(\int_s^t \text{tr}(A(X_u)) du) \sigma(X_s)$. We prove this under general conditions on (X_t) .

ABSTRACT: (U) Let $X=(X_1, \dots, X_d)$ and $V=(V_1, \dots, V_d)$ be processes on $(0,1)$ or R^+ , such that X is exchangeable while V_d is predictable. Under suitable conditions on X and V , the expression $E(\pi_j)$ Integral over j of $(V \text{ sub } j \text{ dx sub } j)$ will only depend on the marginal distributions of X and V . From statements of this type in discrete or continuous time, one may easily derive a variety of old and new results on predictable transformations which preserve the distribution of an exchangeable sequence or process. The same method yields a general result about reduction of continuous local martingales and marked point processes to independent Gaussian and Poisson random fields. Keywords: Stochastic integrals; Product moments; Invariance in distribution; Levy processes; Martingales; Point processes; Brownian bridge; Random time changes.

SUPPLEMENTARY NOTE: Prepared in cooperation with
Minnesota Univ., MN., Rept. no. IMA-244.

ABSTRACT: (U) These lectures aim at giving an elementary introduction to certain types of stochastic differential equations in infinite dimensional spaces. One lecture introduces countably Hilbertian Nuclear (CHN) spaces and give some examples to illustrate why these infinite dimensional spaces are convenient for the study of some practical problems, e.g. those occurring in stochastic evolutions. This lecture assumes a complete probability space with a right continuous filtration. It also assumes a given Countably Hilbertian nuclear space. Ornstein-Uhlenbeck stochastic differential equations on duals of nuclear spaces introduces a special class of linear stochastic differential equations with values in duals of nuclear spaces, namely Ornstein-Uhlenbeck type processes with a nuclear valued martingale as a driving term. Weak Convergence of Solutions: now consider the weak convergence of the solutions of to the corresponding stochastic differential equations driven by a Gaussian noise. This last lecture gives an outline of recent works on stochastic evolution equations and nonlinear

ABSTRACT: (U) A-optimal and MV-optimal repeated measurements designs are given both for direct and residual treatment effects, for comparing several test treatments with a control. The model considered are basically of two types: without preperiods and the circular model. It is shown that some known balanced and strongly balanced uniform repeated measurements designs can be modified to obtain optimal designs for this problem. Some other methods of finding optimal designs are also given. Keywords: Experimental design; Problem solving.

DESCRIPTORS: (U) *OPTIMIZATION, *EXPERIMENTAL DESIGN, CIRCULAR, PROBLEM SOLVING, RESIDUALS, MATHEMATICAL MODELS, ORTHOGONALITY, MEASUREMENT.

ABSTRACT: (U) Experiments have been performed to obtain an understanding of the mechanism of Iodine monofluoride(B) production in the flames of fluorine atoms with various iodides. Measurements have been made of the relative IF(B), I(2P1/2) and I(2P3/2) concentrations in a F/8ismuth triiodide flame under various conditions, including the addition of oxygen (1 delta). The IF(B) vibrational state distributions from a wide range of F atom/iodide flames, both with and without the addition of metastable species such as O2(1 delta) and NF(1 sigma), have a characteristic form, being Boltzmann for the lower vibrational levels but having an excess population for the higher levels. This striking similarity suggests a universal mechanism for IF(B) production. It is proposed that this involves the recombination of an excited iodine atom (2P1/2) with a ground-state fluorine atom. A kinetic model based on this proposal is shown to account for all the measurements. Keywords: Chemiluminescence, Laser fluorescence. (Reprints)

ABSTRACT: (U) A study of the spectroscopic and laser properties of the crystal erbium- and chromium-doped yttrium scandium gallium garnet (Er, Cr:YSGG) has been carried out. The absorption spectra form 300-1700 nm and the emission spectra in the regions around 800, 1600 and 2800 nm have been measured, along with the kinetics of emission and decay under pulsed excitation. Energy levels of the erbium ion have been determined. Analysis of the data shows that energy transfers from excited chromium ions to erbium ions with near-100% efficiency. The 2800-nm-region laser performance of Er,Cr:YSGG, under flashlamp pumping conditions has been observed and found to be superior in some aspects to other erbium-doped crystals. (Keywords: Lasers, Solid State, 2800 nm lasers, Erbium Doped).

ABSTRACT: (U) If we are given a dynamic system with some built-in symmetry, should we except periodic motions which somehow reflect this symmetry? And how would periodicity harmonize with symmetry? We are lead from dynamics to topology algebra, singularity theory, numerical analysis, and to some applications. A global point of view is one guiding theme along the way: we are mainly interested in periodic motions far from equilibrium. For a method we rely on bifurcation theory, on transversality theory, and on generic approximations. As a reward we encounter known local singularities. As a central new aspect we study the global interaction and interdependence of these local singularities, designing a homotopy invariant. As a result, we obtain an index 'H' which evaluates only information at stationary solutions. Nonzero 'H' implies global Hopf bifurcation of periodic solutions with certain symmetries. Putting it emphatically, 'H' harmonizes symmetry and periodicity. Curiously, 'H' need not be homotopy invariant.

ABSTRACT: (U) The main objectives of this research have been the development of smooth nonparametric estimators of quantile functions from right-censored data and the further study of smooth density estimators from censored observations. In particular, kernel type and generalized quantile estimators have been obtained under censoring which give better estimates of percentiles of the lifetime distribution than the usual product-limit quantile estimator. Other new results include the study of linear empirical Bayes estimators, prediction intervals for the inverse Gaussian distribution, nonparametric hazard rate estimation under censoring, nonparametric inference for step-stress accelerated life tests under censoring. Discrete failure models, reliability estimation when cause of failure is partially known, Gompertzian failure models, simultaneous confidence intervals for pairwise differences of normal means, and optimal designs for comparing treatments with a control.

ABSTRACT: (U) Two projects are described: (a) Stability criteria for difference approximations to hyperbolic systems, and multiplicativity of matrix norms; and (b) Problems in applied and computational linear algebra. The aim of these projects was to achieve better understanding of useful computational techniques for hyperbolic initial-boundary value problems, and to improve basic mathematical tools often used in numerical analysis and applied mathematics.

ABSTRACT: (U) W.p.1. convergence results are obtained for stochastic recursive approximation algorithms under very general conditions. The gain sequence (a sub n) can go to zero very slowly and state-dependent noise, discontinuous dynamical equations and the projected or constrained algorithm are all treated. The basic technique is the theory of large deviations. Prior results obtained via this theory are extended in many directions. Keywords: Local linearization; Errors for tracking systems.

DESCRIPTORS: (U) *FINITE DIFFERENCE THEORY, *LINEAR ALGEBRA, APPLIED MATHEMATICS, APPROXIMATION(MATHEMATICS), BOUNDARY VALUE PROBLEMS, COMPUTATIONS, HYPERBOLAS, MATHEMATICAL MODELS, NUMERICAL ANALYSIS, PARTIAL DIFFERENTIAL EQUATIONS, STABILITY.

ABSTRACT: (U) Subjects first detected a target presented at the left of fixation, and then attempted to report, in order, the first four items (numerals or shapes) in a stream of items presented to the right of fixation. At comparably difficult presentation rates, 10/s for numerals and 5/s for shapes, reports showed a mixture of correctly ordered items with items reported in a direction opposite to their order of presentation. Reports fit a three-parameter attention-gating model (AGM), which assumes that (1) after target detection, an attention gate opens briefly to allow items to enter visual short-term memory (VSTM), and (2) report order is determined by the attention each item receives in VSTM. Items presented either early or late in the stream tend to receive less attention and are thus reported as later than more central items. The fit to the AGM for both numerals and unlabelled shapes provides evidence that reports reflect order in short-term visual (rather than verbal) memory.

SUPPLEMENTARY NOTE: Sponsored in part by Contract DAAG29-84-K-0082 and Grant NSF-ECS85-05674.

ABSTRACT: (U) We treat the 'approximately' optimal control problem for tandem queueing or production networks (with local feedback allowed) under heavy traffic. The buffers (scaled with traffic) are finite. The controls allow various inputs, connecting links and the processors to be shut down or opened, in order to manage the system. The service and arrival rates, as well as the routing probabilities can also be controlled, and the system statistics can depend on the system state (scaled buffer occupancies). The associated costs involve holding costs, costs for shutting off/on the links or processors and the opportunity cost for lost production. It is shown that the (scaled) controlled system converges weakly (in an appropriate sense) to a controlled limit 'reflected' diffusion. In the rescaled time, the actions of the controllers lead to multiple 'simultaneous' impulses in the limit problem. Thus we have a non-standard limit control problem, and the usual methods of weak convergence for systems under heavy traffic must be modified. Since the optimal or nearly optimal controls for the physical process are usually not possible to get, it is of considerable interest to know whether an optimal or nearly optimal control for the limit process is also nearly optimal for the physical system with heavy traffic. This is shown to be true, under reasonable conditions. Although the limit control problem is non-standard and

ABSTRACT: (U) The development of solution algorithms for complex flowfields have been the objective of this research. Embedded subdomains were used to resolve relevant physical processes in a global flow around aerodynamic bodies. Both non-adaptive and adaptive approaches were studied and developed. Results for solving the two dimensional Euler equations using non-adaptive and adaptive finite volume and finite element work are summarized. A new approach is reported for combining expert system approaches with adaptive procedural algorithms into a totally integrated methodology. Algorithms for adaptive explicit and non-adaptive semi-implicit Navier-Stokes calculations are reported. Recent results on formulation of outflow boundary conditions for the Navier-Stokes equations are also presented. Keywords: Euler equations; Navier Stokes equations; Finite element methods; Embedded grids; Adaptive grids; Computational fluid dynamics.

ABSTRACT: (U) The authors introduce a new better than
used of age t sub o (NBU t sub o) class of life
distributions, where the survival probability at age 0 is
greater than or equal to the conditional survival
probability at specified age t sub o > 0 . The dual class
of new worse than used of age t sub o (NMU) - t sub o
life distributions is obtained by reversing the direction
of inequality. In Section 3 the authors propose a test of
the null hypothesis that a new item has stochastically
the same residual life length than does a used item of
age t sub o . In Section 4 Pitman's asymptotic relative
efficiency is used to study large-sample power properties
of the test. (Author)

ABSTRACT: (U) Observers matched patches (simulated Munsell papers) in two simultaneously presented computer-controlled displays, a standard array presented under 6500-K illumination and a test array under 4000 or 10,000 K. Adaptation to the test illuminants was limited. The adjusted patch was surrounded by a single color (annulus display) or by many colors (Mondrian display). Observers either matched hue and saturation or made surface-color (paper) matches in which the subject was asked to make the test patch look as if it were cut from the same piece of paper as the standard patch. For two of the three subjects, the paper matches were approximately color constant. The hue-saturation matches showed little color constancy. Moreover, the illumination difference between the two displays was always visible. Our data show that simultaneous mechanisms alone (e.g., simultaneous color contrast) alter hues and saturations too little to produce hue constancy.

ABSTRACT: (U) This report summarizes research accomplishments in the 12 month period Nov. 1, 1985 - Oct. 31, 1986. Significant advances have been made in nonlinear filtering based on robust estimation, on nonparametric detection, and on a new noise model for signal - dependent and multiplicative noise. Reference is made to 11 publications. Keywords include: Nonlinear filters, Robust estimates, Rank estimates, Nonparametric detection, Conditional tests, Quantization, Non-Gaussian noise.

ABSTRACT: (U) Systems with wide bandwidth noise inputs are a common occurrence in stochastic control and communication theory and elsewhere, e.g., tracking or synchronization systems such as phase locked loops (PLL). One is often interested in calculating such quantities as the probability of escape from a desired error set, in some time interval, or the mean time for such escape. Diffusion approximations (the system obtained in the limit bandwidth as the approaches limit of infinity) are often used for this since they are easier to analyze. When the noise effects in the physical system are small, one is tempted to do an asymptotic analysis (noise intensity approaches limit of 0) on the diffusion approximation, and use this for the desired estimates on the original system. Such a procedure does not work in general: the double limit bandwidth approaches limit of infinity, intensity approaches limit of 0 is not always justified. Under quite broad conditions on the noise processes, it is justified for the systems studied here. We study a particular form of the PLL owing to the great practical importance of the system and because it provides a useful vehicle for understanding the extent of validity of the asymptotic methods for such systems. The basic analytical techniques are from the theory of large deviations. One seeks information on the escape probabilities, mean times, and on the most likely exit paths and exit locations. Also, we seek information on the interactions between the signals to be tracked and

AD-A185 768

the noise which are most likely to lead to exit. The large deviations technique is eminently suited to this job. (Reprints)

UNCLASSIFIED REPORT

ABSTRACT: (U) This report summarizes the activities in support of the Air Force Research Project AFOSR-83-0255 during the past year. Efforts have been made to develop, test and analyze new fast techniques in matrix analysis for structural computations and least squares problems. Applications of this work include structural design and dynamics, and least squares filtering in signal processing. Implementations and tests have been made on modern high performance architectures such as the Cray X-MP, Alliant FX/8, Sequent Balance and the Intel iPSC Hypercube. Our recent work on parallel algorithms for near real-time signal processing computations has led to especially significant results. Keywords: Abstracts; Numerical linear; Algebra; Parallel processing; Signal processing, Structural optimization. (Author)

ABSTRACT: (U) The starting point of this investigation is the properties of restricted quadratic forms, x (Transposed) Ax , x an element of S a subset of R superscript m where A is an $m \times m$ real symmetric matrix, and S is a subspace. The index theory of Hestenes (1951) and Maddocks (1985) that treats the more general Hilbert space version of this problem is first specialized to the finite dimensional context, and appropriate extensions, valid only in finite dimensions, are made. The theory is then applied to obtain various inertia theorems for matrices and positivity tests for quadratic forms. Expressions for the inertias of divisors symmetrically partitioned matrices are described. In particular, an inertia theorem for the generalized Schur complement is given. The investigation recovers, links and extends several, formerly disparate, results in the general area of inertia theorems. (Author)

ABSTRACT: (U) This project initiated various aspects of
an ongoing study of numerical/analytic techniques for the
identification of periodic solutions to functional
differential equations. The techniques developed apply to
very general classes of equations, and have been
implemented on a variety of specific model problems.
Local techniques refer to methods that apply to the
problem of analyzing the Hopf bifurcation structure of
small periodic orbits of multiparameter systems. A
FORTRAN code, BIFDE, was written to analyze generic
bifurcations of general systems with infinite delay.
Global tracking methods have been developed to study the
growth and parameter dependence of global Hopf
bifurcations. Investigations have centered on the
development of spine-based approximation techniques and
their implementation in a FORTRAN code FDETRAK. Keywords:
Mathematical programming, Machine coding; Subroutines,
Numerical analysis.

ABSTRACT: (U) The behavior at caustics is analyzed for weakly nonlinear wave solutions of hyperbolic equations. It is shown that short waves, weak enough to be governed by linear or weakly nonlinear geometrical optics away from caustics, are governed by linear theory at and near caustics. For somewhat stronger waves, for which linear theory does not suffice at caustics, a weakly nonlinear caustic theory is developed. It leads to an equation derived by Guiraud, Hayes, and Seebass for gas dynamics.

ABSTRACT: (U) The research conducted under this contract focused on the molecular mechanics of polymeric films in relation to their ultrastructure and nonlinear optical properties aimed towards eventual applications in integrated optical and microelectronic devices. Several landmark results were obtained. They are: (i) First demonstrate of femtosecond of response of nonresonant optical nonlinearity in conjugated polymers. (ii) First demonstration of third-harmonic generation from monolayer film of a conjugated polymer. (iii) First case of a conformational transition in a monolayer film of a conjugated polymer. (iv) First picosecond coherent Raman scattering study of a polymeric system. Our studies of third order optical nonlinearities using picosecond and subpicosecond degenerate four wave mixing as well as third harmonic degeneration established clearly a strong dependence of $\chi^{(3)}$ on the effective pie-electron conjugation. Our study of vibrationally resonance enhanced nonlinearity using coherent Raman scattering revealed an enhancement by two orders of magnitude with response still in picoseconds. The Langmuir-Blodgett method was applied for the preparation of monolayer and multilayer films of several types of polydiacetylenes. Our study showed that the Langmuir-Blodgett technique can successfully be used for molecular engineering of ultrathin polymeric films with monomolecular control. Other techniques used for the preparation of ultrathin

ABSTRACT: (U) For an undirected network $G=(V,E)$ whose arcs are subject to random failure, we present a relatively complete and comprehensive description of a general class of Monte Carlo sampling plans for estimating $g(s,t)$, the probability that a specified node s is connected to all nodes in a node set T . We also provide procedures for implementing these plans. Each plan uses known lower and upper bounds B , A on g to procedure an estimator of g that has a smaller variance ($A-g|g-B|/K$ on K independent replications than that obtained for crude Monte Carlo sampling ($B=0$, $A=1$). We describe worst-case bounds on sample sizes K , in terms of B and A , for meeting absolute and relative error criteria. We also give the worst-case bound on the amount of variance reduction that can be expected when compared with crude Monte Carlo sampling. Two plans are studied in detail for the case $T=t$. An example illustrates the variance reductions achievable with these plans. We also give the worst-case bound s on the amount of variance reduction that can be expected when compared with crude Monte Carlo sampling. Two plans are studied in detail for the case $T = t$. An example illustrates the variance reductions achievable with these plans. We also show how to assess the credibility that a specified error criterion for g is met as the Monte Carlo experiment

ABSTRACT: (U) This paper considers the problem of designing control laws for linear systems with time varying uncertainty. Lyapunov stability theory is used to develop a numerical method of finding a control law that asymptotically stabilizes such systems. This control is robust in the sense that it guarantees asymptotic stability regardless of the disturbance. The results are applied to several aircraft examples. Keywords: Uncertain systems; Stability; Robust control; Linear control problems.

ABSTRACT: (U) This technical program constitutes a theoretical research investigation of the kinetic mechanisms of negative ion information in plasmas. This study was directed toward elucidating the mechanisms of the most important volume-dependent reactions that occur in hydrogen-ion H-(D-) source devices, primarily of the Belchenko-Dimov-Dudnikov (BDD) type and toward evaluating other light negative anions, such as Li-, as possible sources. The primary goal of this research program was to identify the most important reactions leading to negative ion production or destruction and to estimate these reactions rates as a function of system parameters such as density, composition and temperature. A further goal was to explore new chemical sources for the production of light mass negative atomic ions. The results of this program furnish data and provide direction for more detailed investigations into the kinetics of both gas phase and gas-surface reaction rates of importance in ion source devices and provide input for reliable modeling of such systems. This investigation was carried out using quantum mechanical methods. Both ab initio and density functional approaches were employed in these studies.

SUPPLEMENTARY NOTE: Pub. in Jnl. of Materials Science, v22 p1006-1011, 1987.

ABSTRACT: (U) In this study the material damping of laminated composites is derived analytically. The derivation is based on the classical lamination theory in which there are eighteen material constants in the constitutive equations of laminated composites. Six of them are the extensional stiffness designated by A six of them are the coupling stiffness designated by B and the remaining six are the flexural stiffness designated by D. The derivation of damping of A, B, and D is achieved by first expressing A, B and D in terms of the stiffness matrix Q(k) and h_k of each lamina and then using the relations of Q_{ij}(k) in terms of the four basic engineering constants E_L, E_T, G_{LT}, and ν_{LT}. Next we apply elastic and viscoelastic correspondence principle by replacing E_L, E_T... by corresponding complex modules E*_L, E*_T..., and A by A*, B by B* and D by D* and then equate the real parts and the imaginary parts respectively. Thus we have expressed A_{ij}, B_{ij}, and D_{ij}, and Q_{ij}, in terms of the material damping N(k)_L and N(k)_T... of each lamina.

ABSTRACT: (U) Trapped energy modes in the piezoelectric thin film on semiconductor composite resonator are explained and contrasted with modes that do not trap energy. The results of calculations of the quality factor of the fundamental essentially thickness-extensional mode in the composite resonator due to radiation into the bulk semiconductor wafer are discussed. The combination of materials considered was aluminum-nitride on gallium-arsenide. The calculations show that when trapping is not present the quality factor is a very rapidly varying function of the ratio of the composite resonator thickness to the wafer thickness and that the range of variation is very large, i.e., between one and two orders of magnitude. The calculations also reveal that when trapping is present the quality factor is always much larger and its range of variation with thickness ratio much smaller than when trapping is not present. The direct calculation procedure is required to check the accuracy of a perturbation procedure. The perturbation procedure for the calculation of the quality factor of the composite resonator due to radiation into the semiconductor wafer is discussed. The perturbation procedure enables calculations for the case of rectangular electrodes and diaphragms to be performed.

ABSTRACT: (U) Chemiluminescence has been studied for the reactions of fluorine atoms with a range of inorganic iodides. From the form of the resulting IF(B) vibrational state distributions, it is concluded that in all F/iodide systems IF(B) is produced by the recombination of a fluorine atom with an excited iodine atom. This is supported by the results of VUV laser-fluorescence probing and kinetic modelling. Keywords: Chemiluminescence, Iodine monofluoride, Iodine atoms, Fluorine atoms, Chemical laser, Laser fluorescence.

UNCLASSIFIED REPORT

ABSTRACT: (U) A multi-element research program was conducted to improve understanding of the role of cascade losses in compressor post-stall behavior. Experiments in a special wind tunnel designed for high-angle-of-attack investigations included surface and smoke flow visualizations and hot film anemometer velocity measurements. Results showed the details of the stall development in a cascade, and the effect of stagger on measured flow losses. Predictions of a Navier-Stokes model for separated cascade flows were compared with experimental results. An improved compressor stage model predicts post-stall characteristics, and illustrates the application of the results to compression system analysis. Keywords: Cascades (Fluid dynamics); Flow measurements; Stalling behavior; Propagating stalls.

ABSTRACT: (U). The funded project was designed, initially
to explore the effects of hydrazines upon cyclic
nucleotide regulated neuronal processes. Cyclase as it
was discovered that hydrazines were potent activators of
this enzyme. In order to understand hydrazine actions in
the CNS, it was required that more basic knowledge of the
adenylate cyclase cascade by accumulated and this study
probed some of the distinctions between neural and non-
neural adenylylase cyclase with that in mind. Specifically,
the following has been accomplished during the project
period: Interactions between the cytoskeleton and
synaptic membrane adenylylase cyclase have been probed and
we have found a reversible attachment between the GTP-
binding proteins regulating adenylylase cyclase and that
membrane. We have discovered that GTP binding proteins
directly interact and may exchange nucleotide with one
another, and have hypothesized this mechanism as an
intracellular regulator of signal transduction. We have
discovered a novel, neural GTP binding protein and are in
the process of purification and characterization. We have
devised a method for measuring adenylylase cyclase in
monolayers of permeable cells and have used this method
to explore the coupling between receptors and adenylylase
cyclase GTP-binding proteins. It is hoped that an
increased understanding of the neuronal adenylylase cyclase

ABSTRACT: (U) Visible chemiluminescence in the region 200-900 nm was measured for the reactions of Fluorine atoms with methane, methyl iodide, CD3I, CH2I2, CHI3 and CI4 studied at reduced pressure (ca. 0.6 mbar). Emission was observed from electronically excited IF (B), HCF (A), CH (A) and C2 (d) and from vibrationally excited HF. Vibrational populations and rotational temperatures were obtained for the diatomic emitters. The reaction F + CI4 was found to produce IF (B) with a non-thermal vibrational population distribution that has excess population in the higher vibrational levels. Possible mechanisms for the formation of the emitters are discussed. Keywords: Chemiluminescence, Iodine monofluoride, Organic Iodides.

ABSTRACT: (U) Diversity of bugs or faults in a software system is a factor contributing to software unreliability which has not yet been appropriately emphasized. This paper is written with the intention of demonstrating the impact of fault diversity on the time to detection of software bugs. A new discrete software reliability model based on the multinomial distribution is introduced. It is shown that for models of this type, the more diverse the fault probabilities are, the longer it takes to detect or eliminate any n faults, while the smaller will be the number of faults detected or eliminated during a given amount of time (or during a given number of inputs to the system). The impact of fault diversity is also demonstrated for the Jelinski-Moranda model. (Author)

UNCLASSIFIED REPORT

ABSTRACT: (U) This document considers a linear regression model, where $(x \text{ sub } i)$ is a sequence of experimental points, i. e., known p-vectors, $(e \text{ sub } i)$ is a sequence of independent random errors, with $\text{med}(e \text{ sub } i) = 0$, $i = 1, 2, \dots$. Define the minimum L1 -norm estimate of $(\alpha, \beta)'$, by $(\alpha, \beta)'$, to be chosen such that under quite general conditions on $(x \text{ sub } i)$ and $(e \text{ sub } i)$, the strong consistency of the minimum L1 -norm estimate is established. Further, under an additional condition on $(x \text{ sub } i)$, it is also proved that for any given $\epsilon > 0$, there exist constant $C > 0$ not depending on n .

ABSTRACT: (U) Much of the recent work on modeling repairable systems involves Poisson processes with nonconstant intensity functions, viz, nonhomogeneous Poisson processes. Since times between failures are not identically distributed when the process is nonhomogeneous, it is not clear what concept should take the place of the mean time between failures in assessing the reliability of a repairable system. A number of alternate concepts can be found in the literature. We investigate the relationship between two of the most frequently considered alternatives; the reciprocal of the intensity function, and the mean waiting time from i until the next failure. Theorem 1 states a necessary and sufficient condition for the mean time until the next failure to be asymptotically proportional to the reciprocal of the intensity function. Some examples, including the familiar log-linear and power-intensity processes satisfy this condition. A monotonicity property is also established between these two concepts which could be used to obtain conservative statistical confidence limits for the mean time until the next failure, based on results which are already available for the intensity function of the power-intensity process. However, further study of concepts such as the rate of convergence would be needed in order to determine the

degree of approximation of the nominal confidence level to the actual level. Until more is known about the mean time from t until the next failure, it would be advisable to use the reciprocal of the intensity function, which has been studied more extensively, as the basis of reliability assessment for a repairable system. UNCLASSIFIED REPORT

ABSTRACT: (U) Two necessary components of any image understanding system are on object recognizer and a symbolic scene representation. The LandScan system currently being designed is a query driven scene analyzer in which the user's natural language queries will focus the analysis to pertinent regions of the scene. This is different than many image understanding systems which present a symbolic description of the entire scene regardless of what portions of that picture are actually of interest. In order to facilitate such a focussing strategy, the high level analysis which includes reasoning and recognition must proceed using a top-down flow of control, and the representation must reflect the current sector of interest. In order to facilitate such a focussing strategy, the high level analysis which includes reasoning and recognition must proceed using a top-down flow of control, and the representation must reflect the current sector of interest. This paper proposes the design for a goal-oriented object recognizer and a dynamic scene representation for LandScan a system to analyze aerial photographs of urban scenes. The recognizer is an ATN in which the grammar describes sequence of primitives which define objects. The Scene

ABSTRACT: (U) Conceptual designs of potentially attractive high-performance thrusters are defined. These are a kw steady-state radiation-cooled DC thruster and a MW quasi-steady DC thruster. These thrusters offer the potential for long operating life with low erosion rates and 50 to 100% improvements in performance over prior plasma thrusters. The kw thruster would be a prototype of a radiation-cooled electric thruster for future electric propulsion missions. The MW thruster would be an inexpensive experiment to define the potential of subsequent very-high power, steady-state thrusters which would utilize superconducting magnets. The kw thruster would use xenon propellant and the MW thruster would use argon propellant. Both should operate at efficiencies of 50 to 80% in the 2500 to 3000 second specific impulse range. Keywords include: Electric propulsion; Plasma, Electrothermal, and MPD thrusters.

UNCLASSIFIED REPORT

ABSTRACT: (U) The Optical Transistor and Switch, for which concepts and designs were developed under this program, is a device in which a radiation beam of one wavelength is controlled by a beam of a second wavelength. In contrast to other optical transistors and switches, this arrangement keeps the requirements for control and signal independent and thus adds another dimension to design. The basic device provides simply an optical path through a medium which consists of of free three-energy level atoms such as sodium vapor at very low pressures. It provides, with relatively low optical powers, satisfactory switching action and transistor saturation gains of 3-10. A subsequent concept is that of Multistate Optical Transistors based on spectroscopically complementary materials. Very high transistor gains can be achieved with two variations of this concept. However, the higher optical power demand and the stringent requirement of double resonance between two materials are important drawbacks. The third concept is the Quantum Transition Etalon which consists of a Fabry-Perot cavity enclosing the three-level medium. The QTE appears to have substantially the advantages of the two former concepts.

UNCLASSIFIED REPORT

ABSTRACT: (U) Experimental and theoretical efforts aimed at clarifying and revealing important dynamical features of several turbulent shear flows are described. The flows studied include boundary layers, jets, wakes and separated flows on lifting surfaces. Significant progress has been made through experimental studies toward understanding: (i) processes in turbulent boundary layers responsible for the production of turbulent energy via local, inflectional-instability events and the modification of boundary layer growth and entrainment by passive large-eddy manipulation devices; (ii) procedures for enhancing entrainment and mixing in jets either by actively forcing the flow or by passively contouring the jet exit; and (iii) characteristics of boundary layer separation and its control on lifting surfaces in unsteady flows. Theoretical studies on the temporal and spatial structure in blunt-body wakes have revealed the necessary conditions under which global, self-sustained oscillations appear and, also, have provided firm criteria for specifying the frequency of these oscillations. The results are consistent with existing experimental evidence and suggest promising approaches for drag modifications for flow over bluff bodies. Several experimental facilities have been designed. Keywords: Separated flows; Unsteady flows; Turbulent

Applications, v87 p273-278 1987.

ABSTRACT: (U) Few parts of applications-oriented mathematics have benefited from the interaction with modern algebraic and analytic geometry as much as the area usually referred to as multidimensional systems theory. This field consists of the study of various topics in the theory of functions of several complex variables, motivated mostly by problems in network design and synthesis and by signal-processing applications. Because of finite realizability constraints, the focus is often on rational functions; this accounts for the strong algebraic flavor of papers in the area, and in particular the use of techniques and results from commutative algebra. A linear-algebraic component is introduced by the need to consider matrices whose entries are analytic or rational functions. Multidimensional systems appear when dealing instead with partial differential (or difference) equations. The independent variables may now represent different space coordinates (as in image processing applications), or perhaps mixed time and space variables (as in seismic data processing). Multidimensional models are also useful when studying certain types of functional differential equations in one independent variable, as delay-differential systems.

ABSTRACT: (U) The authors consider a system consisting of a rigid body to which a linear extensible shear beam is attached. For such a system the Energy-Casimir method can be used to investigate the stability of the equilibria. In this case, it can be shown that a test for (formal) stability reduces to checking the positive definiteness of two matrices which depend on the parameters of the system and the particular equilibrium about which the stability is to be ascertained. Keywords: Computations; Variations; Configurations. (Author)

UNCLASSIFIED REPORT

ABSTRACT: (U) This paper examines multivariate nonparametric classes and methods in reliability. Hollander and Proschan (1984) described the various univariate nonparametric classes in reliability. The classes of adverse aging described include the IFR, IFRA, NBU, NBUE, and DMRL classes. The dual classes of beneficial aging are also covered. Several new univariate classes have been introduced since that time. One that this document briefly mentions is the HNBUE class, since we are aware of several multivariate generalizations of this class. The univariate classes in reliability are important in applications concerning systems where the components can be assumed to be independent. In this case the components are often assumed to experience wearout or beneficial aging of a similar type. For example, it is often reasonable to assume that components have an increasing failure rate (IFR). In making this IFR assumption it is implicit that each component separately experiences wear and no interactions among components can occur. However in many realistic situations, adverse wear on one component will promulgate adverse wear on other components. From another point of view a common environment will cause components to behave similarly. In either situation, it is clear that an assumption of independence on the components would be valid.

ABSTRACT: (U) An algebraic structure underlying network reliability problems is presented for determining the 2-terminal reliability of directed networks. An iterative algorithm is derived from this algebraic perspective to solve the (s, j) -terminal reliability problem simultaneously for all nodes j . In addition to providing an exact answer (in the form of a reliability polynomial), the algorithm also yields a nondecreasing sequence of approximate solutions guaranteed to be lower bounds on the exact solution. Empirical results, presented for two different implementations of the algorithm, show that useful approximate solutions can be obtained in a reasonable amount of computation time.

ABSTRACT: (U) This project explored fast algorithms for Euler and Navier Stokes simulations. A particular issue pursued under the grant was the integration of an explicit three dimensional flow solver. Embedded mesh refinements, a model equation hierarchy, multiple grid acceleration and extensive rectorization and multi tasking. Several papers were produced during this effort including such titles as 'Multitasked embedded multigrid for three-dimensional flow simulation' and 'Multigrid approaches to the Euler equations'. An efficient algorithm designed to be used for Navier Stokes simulations of complex flows over complete configurations is described. The algorithm incorporates a number of elements, including an explicit three-dimensional flow solver, embedded mesh refinements, a model equation hierarchy ranging from the Euler equations through the full Navier-Stokes equations, multiple-grid convergence acceleration and extensive vectorization and multitasking for efficient execution on parallel processing supercomputers. Results are presented for a preliminary trial of the method on a problem representative of turbomachinery applications. Based on this performance data, it is estimated that a mature implementation of the algorithm will yield overall speedups ranging as high as 100.

UNCLASSIFIED REPORT

ABSTRACT: (U) The equations for the spatial and temporal modulations of the phase shift for slowly varying strongly nonlinear oscillators and dispersive waves have been determined for the first time. The effects of dissipative perturbations have been investigated for nonlinear oscillatory solutions of ordinary and partial differential equations (described by Klein-Gordon and Korteweg-de Vries type equations). The phase shift equations were derived using the method of multiple scales by evaluating the small perturbations to the exact action equation, a somewhat simpler technique than usual elimination of secular terms at an even higher order in the asymptotic expansion. It has been shown that, for dissipative perturbations, the frequency and action equations are valid to higher order and that their variations are only due to perturbations in the wave number and the averaged amplitude parameters. For second-order ordinary differential equations, the phase shift is determined from initial conditions in straight-forward manner since it was shown that there exists a new adiabatic invariant.

UNCLASSIFIED REPORT

ABSTRACT: (U) Automating rule strengths in expert systems is a way to alleviate the knowledge acquisition bottleneck. It is assumed that rules are fixed, except for the values of their strengths, which are computed or adjusted from initial values given by experts. A model of expert systems is proposed, in which rules have the form IF (P sub 1 & P sub 2 & . . . & P sub n) THEN C WITH ATTENUATION a, where P sub 1, P sub 2, . . . , P sub n, and C are weighted propositions, i.e., statements with a certainty factor (CF), and a, the strength of the rule, is a number between 0 and 1. To compute rule attenuations, two problem settings are considered. In the first, an oracle is given, that can provide the CFs of the conclusions of the entire rule-based system, given any assignment of certainty factors to the premises of the entire system (complete case). In the second, a fixed set of cases is available (incomplete case). A fast algorithm for synthesis in the complete case for simple rule bases is given both for MAX and probabilistic sum. In the incomplete case, the synthesis of attenuations is shown to be NP-complete, even for very shallow rule bases with only two propositions in the premise of each rule, both for MAX and probabilistic sum. The refinement of attenuations from expert-given estimates is shown to be NP-hard, no matter how close to the correct value the estimates are and how small an improvement towards the correct value is desired. UNCLASSIFIED REPORT

ABSTRACT: (U) The most fundamental problem in the entire theory of oscillations is to describe the motion of a mass point, the tip mass, attached to a spring. Within the classical theory of particle mechanics, the spring is regarded as massless, so that it serves only to transmit a force to the tip mass. This force typically depends on the position and velocity of the tip mass in perhaps a nonlinear way. In this case, the motion is governed by an autonomous ordinary differential equation. On the other hand, if the spring has mass, then its motion as a continuum is coupled to that of the tip mass. If the spring has a nonlinear constitutive equation, then the analysis of the resulting motion, governed by partial differential equations, can be formidable indeed. This paper studies the motion of both tip mass and spring when the mass density of the spring is small and when its constitutive equation describes nonlinearly elastic and viscoelastic materials. Although these constitutive equations do not account for past history, if its nevertheless proven that in the formal limit as the spring's mass density goes to zero the equation for the tip mass is an ordinary differential equation for elastic springs, but is generally not so for viscoelastic springs.

ABSTRACT: (U) Numerical simulations of hypersonic shear flow, utilizing the full-time-dependent compressible flow Navier-Stokes equations, have been carried out to demonstrate the feasibility of exposing, computationally, the essential structure/physics of turbulent fluctuations in high speed flow. The geometry employed is one of interest to the U.S. Air Force in various applications, namely a right circular cylinder whose axis is aligned with the on-coming flow and around which the cylinder could be rotated. By simulating the flow along a cylinder of the infinite axial extent, an exceptionally quiet flow was established. Due to limitations of computational time, it was necessary to excite artificially this flowfield with periodic suction and blowing located well upstream of the observation plane. As a result, fluctuations in the flowfield entropy, vorticity and pressure were observed which revealed a distinct Mach number dependence. At hypersonic Mach numbers, the fluctuating entropy defined a second boundary layer edge, well beyond that of the vorticity but not propagating deep into the inviscid flow, as was observed in both transonic and supersonic regimes.

ABSTRACT: (U) Our work has concentrated on developing a unifying framework, under the name UNITY, for studying problem-solving in parallel programming independent of specific architectural considerations. We have proposed a simple model of computation and a logic to reason about properties of such programs and have managed to study problems from a variety of problem areas. We have developed a number of transformations which are appropriate for implementations on a variety of architectures: sequential, asynchronous shared memory, distributed message passing, synchronous parallel with shared memory, systolic arrays, and VLSI chips. The diversity of the application areas and the architectures studied lends credence to our hypothesis that there is a UNITY to programming.

ABSTRACT: (U) A correspondence is established between a family of inverse scattering problems, including filter synthesis and seismic exploration, and a family of matrix factorization problems, including stochastic filtering, stability testing, partial/stochastic realization and model order reduction. This correspondence originates from the notion of energy conversation (i.e., losslessness), and it involves computational procedures whose signal-flow-graph representation is a lossless cascade network. Our analysis of recent results on efficient triangular factorization of Hermitian matrices indicates a possible extension of the network-theoretic notion of losslessness. (Reprints)

ABSTRACT: (U) An investigation of an oblique shock wave/
laminar boundary layer interaction is presented. The Mach
number was 2.15, the Reynolds number was 100,000 and the
overall pressure ratio was 1.55. The interaction has been
demonstrated to be laminar and nominally two dimensional.
Experimental results include pressure distributions on
the plate in the attached and separated regions. The
numerical results have been obtained by solving the full
compressible Navier-Stokes equations with the implicit
approximate factorization algorithm by Beam & Warming
(1980). Comparison with experimental data shows good
agreement in terms of pressure distributions, positions
of separation and reattachment and velocity profiles.
Keywords: Supersonic flow. (Reprints)

ABSTRACT: (U) The maintenance of large volatile
knowledge bases is the focus of this project. The
viewpoint from which the study is being conducted is that
of certain extensions of current logic programming
systems, primarily the so-called metalanguage systems in
which a logic programming language is amalgamated with a
portion of its metalanguage. Major thrusts of the work
include (1) study of the extent to which such
representation mechanisms as frames and semantic nets can
be logically treated (thus yielding a measure of
independence of representation for the rest of the work),
and (2) the use of the metalanguage facilities for the
maintenance of consistency and integrity under change and
other questions of analysis of the knowledge base.
Computer-based systems to aid human intelligence analysts
are instances of a generic class of systems known as
tracking systems. Such systems minimally consist of
knowledge base in which records representing the
analyst's concerns are stored. A useful organization of
such knowledge bases distinguishes between events and
event-lines. Events are relatively discrete in time, such
as signal reports or activity reports, while event-lines
are extended, continuous sequences of events. Events may
be thought of as discrete points, plotted on some event-
line. One may also impose a hierarchical structure
among event-lines with individual event-lines

ABSTRACT: (U) This paper proposes a notion of smooth
action on a manifold, and establishes a general
integrability result for certain associated distributions.
As corollaries, various classical and new results on
manifold structures of orbits are established, and the
main theorem on preservation of transitivity under
sampling is shown to be a simple consequence. One of the
basic results in control theory, states that, for
continuous time systems, each orbit (set accessible with
positive- and negative-time motions from a given starting
state) has a structural of immersed submanifold of the
state space. This structure is obtained, roughly, as
follows. Given any piecewise constant control steering a
state into the state x_i this control having switches at
times t_1, \dots, t_{k-1} , tangent vectors to the orbit
at x_i are obtained by taking perturbations of the t sub i .
(More precisely, positive- and negative- time controlled
motions are used.) When phrased in terms of the
integrability of an associated distribution, this
generalizes classical theorems of Frobenius and Chow.

ABSTRACT: (U) In search for the best of n candidates,
two-stage procedures of the following type are in common
use. In a first stage, weak candidates are removed, and
the subset of promising candidates is then further
examined. At a second stage, the best of the candidates
in the subset is selected. In this article, optimization
is not aimed at the parameter with largest value but
rather at the best performance of the selected candidates
at Stage 2. Under a normal model, a new procedure based
on posterior percentiles is derived using a Bayes
approach, where nonsymmetric normal (proper and improper)
priors are applied. Comparisons are made with two other
procedures frequently used in selection decisions. The
three procedures and their performances are illustrated
with data from a recent recruitment process at a
Midwestern university. (Keywords: Screening; Scoring;
Standard; Deviation; Reprints). (Author)

UNCLASSIFIED REPORT

ABSTRACT: (U) When people use language spontaneously they often do not adhere strictly to commonly accepted standards of grammaticality. The primary objective of this project is to develop flexible computer parsing techniques which can deal with the various kinds of ungrammaticalities that arise, both on the lexical and the phrase level. The progress towards this goal covered by this report includes: 1) The initial development of the FlexP flexible parser based on pattern-matching techniques; 2) Review of the initial design choices for FlexP in the light of this evaluation, leading to the formulation of the construction-specific approach to parsing, and its preliminary evaluation for applied natural language processing through the experimental parsers CASPAR and DYPAR; 3) Application of the construction-specific approach to flexible parsing to the parsing of an artificial command language in the parser for the Cousin command interface, a graceful interface for the Unix operating system; 4) Investigation of control structures that would allow the integration of multiple diverse parsing strategies into a single parsing system in an extensible manner; 5) Development of a taxonomy of grammatical deviations and recovery strategies for dealing with them; 6) Design and implementation of an initial version of MULTIPAR, the

UNCLASSIFIED REPORT

ABSTRACT: (U) This paper is primarily concerned with computing first passage time statistics. In previous work a general reliability model was proposed in which system failures occur when either system wear-and-tear reaches some maximum permissible level (ie, a first passage occurs), or when some killing event happens (such killing events occur with rate $k(x)$ in state x). Under this model $w(x,t)$ satisfies a certain equation: It is possible to solve for $w(x,t)$ and related quantities with methods very similar to those presented here. In Section 2, algorithms for approximating $w(x,t)$ are obtained. In particular, the infinite spectral expansion for $w(x,t)$ is approximated by an n -term sub-expansion which matches the first $n-1$ moments. Section 2 concludes with some remarks about out preliminary computational experience. In Sections 3 and 4, methods are given for obtaining the eigenvalues and first passage moments, necessary for computing approximations to $w(x,t)$. In Section 5, computational issues related to calculating the moment generating function are considered. Section 6 and 7 include theoretical complements about first passage times. In particular, the moment generating function is shown to possess an interesting representation having exponential form. This exponential representation is related to asymptotic expansions used in analyzing perturbations of certain second-order differential equations.

ABSTRACT: (U) This document presents autoregressive (AR) and autoregressive moving average (ARMA) processes with bivariate exponential (BE) and bivariate geometric (BG) distributions. The theory of positive dependence is used to show that in various cases, the BEAR, BGAR, BEARMA, and BGARMA models consist of associated random variables. The authors discuss special cases of the BEAR and BGAR processes in which the bivariate processes are stationary and have well known bivariate exponential and geometric distributions. (Author)

ABSTRACT: (U) This volume is an executive summary of the research project on centrifugal and numerical modeling of buried structures subjected to static and dynamic loadings on the ground surface. Techniques were developed for testing model buried pipes in a geotechnical centrifuge. An impact generator was developed for applying an airblast loading on the centrifuge model. A dynamic stress gage was developed for measuring the stresses generated in the soil and acting on the buried pipe during the airblast loading. Finite element analyses were performed on the buried pipe experiments. Comparison between centrifuge test data and analytical results is used to validate the numerical analysis procedure. Keywords: Soil-structure interaction; Centrifuge model testing; Static loading.

ABSTRACT: (U) This report covers activities of John R. Rice (PI) and associates since October 1984. The activity of Kai Hwang is reported separately because it is being proposed that this grant be separated into two parts due to Kai Hwang's change of position to the University of Southern California. The activities include (1) The completion and submission for publication of one technical paper on expert systems for partial differential equations, (2) The completion of one report on high level parallel languages for multiprocessors, (3) One manuscript to be presented at a conference in October 1985, (4) Three manuscripts in progress on the use of supercomputers, the use of distributed multiprocessor systems for PDEs and new numerical methods, (5) Considerable process in the analysis and high level restructuring of several important PDE algorithms for parallel execution. Independently of this grant, the investigators have just obtained a multiprocessor machine (the FLEX 32) which will greatly enhance the research program. (Author)

ABSTRACT: (U) Given that an item is of age t , the expected value of the random remaining life is called the mean residual life (MRL) at age t . We propose two new nonparametric classes of life distributions consists of those with 'increasing initially, then decreasing mean residual life' (IDMRL). The IDMRL class models aging that is initially beneficial, then adverse. The second class, decreasing, then increasing mean residual life (IDMRL), models aging that is initially adverse, then beneficial. We propose two testing procedures for H sub 0: constant MRL (i.e., exponentially) versus H sub 1: IDMRL, but not constant MRL (or H sub 1: DMRL, but not constant MRL). The first testing procedure assumes the turning point, τ , from IDMRL to MRL is specified by the user or is known. The second procedure assumes knowledge of the proportion, ρ , of the population that dies at or before the turning point (knowledge of τ itself is not assumed).

ABSTRACT: (U) This paper discusses the effect of measurement errors in both variables when using the simple linear regression model. It is often stated that if the measurement error in x is small, then we can ignore this error and fit the model to data using ordinary least squares. There is some ambiguity in the statistical literature concerning the exact meaning of a small error. For example, Fraper and Smith (1981) state that if the measurement error variance in x is small relative to the variability of the true x 's, then 'errors in the x 's can be effectively ignored'. See Montgomery and Peck (1983) for a similar statement. Scheffe (1973) and Mandel (1984) argue for a second criterion, which may be informally summarized that the error in x should be small relative to (the standard deviation of the observed y about the line)/(slope of the line). We argue that for calibration experiments, both criteria are useful and important; the former for estimation of x given y , and the latter for the lengths of confidence intervals for x given y .

ABSTRACT: (U) The authors consider a K out of N system maintained by R repairmen, where the lifetime of the i sub th component is an exponentially distributed random variable with parameter micron sub i. Repairmen are distinguishable, and the time it takes the r sub th repairmen to repair a failed component is an exponentially distributed random variable with parameter lambda sub k. Repaired components are as good as new and preemptions are allowed. It is shown that the policy which assigns the faster repairmen to the most reliable components is optimal with respect to several optimality criteria. The approach taken in establishing stochastic optimality with respect to the number of functioning components is of wide applicability to different classes of stochastic optimization problems. ABSTRACT: (U) This paper examines the problem of estimating the state of a distributed finite-state Markov process consisting of several interacting finite-state systems each of whose transition probabilities are influenced by the states of the other processes. The observations on which the estimation procedure is based are continuous signals containing signatures indicative of the occurrence of particular events in the various finite-state systems. The problem of electrocardiogram analysis serves both as the primary motivation for this investigation and as the source of a case study we describe in the paper. The principal focus of the paper is on the development of an approach that overcomes the combinatorial explosion of truly optimal estimation algorithms. The authors accomplish this by constructing a systematic design methodology in which the resulting estimator consists of several interacting estimators, each focusing on a particular subprocess. Important questions addressed concern the way in which these estimators interact and the method each estimator uses to account in its own model for the influence of other subprocesses.

UNCLASSIFIED REPORT

ABSTRACT: (U) Classical iterative schemes such as the Gauss-Seidel method and its variations constitute powerful tools for computing stationary distribution vectors for large-scale Markov process, such as those arising in queueing network analysis. The coefficient matrix A in these processes is a Q -matrix, i.e., a singular irreducible M -matrix with zero column sums and, unlike the nonsingular case, the classical iterations for A do not always converge. The purpose of this paper is to survey the recent literature and to analyze the behavior of these methods completely in terms of the graph structure of A . The results given here hold under somewhat weaker assumptions on A . Keywords: Markov chains, queueing networks, Stochastic processes. (Author)

ABSTRACT: (U) Let M be a two-parameter continuous martingale bounded in L^2 and null on the axes. The positive submartingale M^2 has a Doob-Meyer decomposition. The purpose of this paper is to relate the measures induced by certain quadratic variations in terms of the absolute continuity property. Since we are dealing with random measures, different definitions are possible. Keywords: Convergence; Theorems; One dimensional; Stochastic processes.

ABSTRACT: (U) The focus of this work was to study large volatile knowledge bases. The research involved developing extensions to logic programming systems in the form of a metalanguage, by studying to what extent frames and semantic nets could be employed. The management of consistency and integrity under change using a metalanguage was analyzed. This research produced a rule-based deductive programming language, called metaProlog, which enhances Prolog's ability to manipulate the databases themselves and to reason about them. This was accomplished by regarding databases (or theories) as first-class objects capable of being passed as arguments. Four papers were published under this grant, including Meta-kavek programming and knowledge representation and metaProlog: A metalevel extension to Prolog. (Author)

UNCLASSIFIED REPORT

ABSTRACT: (U) Details of the turbulence production process in turbulent boundary layers in the wall region have been clarified, especially the formation of the long streaky structure, and secondary hairpin vorticity. It appears that the outer region microscale coherent motion called a typical eddy plays the dominant role in the process. Long time averaged statistics of the two point vorticity-vorticity correlations support the conditionally sampled data and interpretations. The typical eddy produces the long streaks along with the pockets, and one of the hairpins directly. Several other hairpins form from the evolution of the vorticity produced by the passage of the typical eddy over the wall. A model of the typical eddy/wall region interaction, i.e., a vortex ring/Stokes layer interaction, was investigated to see if it could reproduce all of the morphology. It was found that the model can produce all of the turbulent boundary layer features associated with production, including the long streaks. By using the model, we have gained new insights into the sensitivity of the production process. Relatively small differences in the convection velocity of the excitation eddies have been found to result in the difference between turbulent

ABSTRACT: (U) Under the supervision of principal investigator R.H. Rand, software has been written in MACSYMA which automatically performs normal form computations for systems of nonlinear nonautonomous differential equations. We have produced a package which permits the user to perform Taylor expanded near identity transformations with unevaluated coefficients on a system of autonomous ODE's (valid to terms of arbitrary order), and then to choose the transformation coefficients so that the resulting system is in normal form. This work has been applied to the nonlinear parametric stiffness control of flexible systems by Professors Moon and Rand, and to the dynamics of coupled van der Pol oscillators.

UNCLASSIFIED REPORT

ABSTRACT: (U) An algorithm for the Satisfiability problem is presented and its probabilistic behavior is analysed when combined with two other algorithms studied earlier. The analysis is based on an instance distribution which is parameterized to simulate a variety of sample characteristics. The algorithm dynamically assigns values to literals appearing in a given instance until a satisfying assignment is found or the algorithm gives up without determining whether or not a solution exists. It is shown that if n clauses are constructed independently from r boolean variables where the probability that a variable appears in a clause as a positive literal is p and as a negative literal is p then almost all randomly generated instances of satisfiability are solved in polynomial time under certain conditions. Thus the combined algorithm is very effective in the probabilistic sense on instances of SAT that have solutions.

ABSTRACT: (U) The Goose Bay HF radar is a sophisticated instrument capable of providing detailed information on very high latitude E and F region ionospheric electron density irregularities which act as a source of clutter on OTH radar systems. Through the use of two parallel phased array antennas, this instrument is able to image the location of these irregularities within a three-dimensional volume covering much of northeastern Canada and Greenland. It is also capable of following the temporal variability of these irregularities as well as determining unambiguously the Doppler shift and broadening of radar signals scattered by them. This paper presents initial results with a single phased array antenna which represent typical examples of the spatial intensity distribution of these irregularities at different local times. Examples are presented of Doppler spectra of the irregularities at different local times. Data of this type are of appreciable value in ascertaining the techniques that must be utilized to improve clutter mitigation on high latitude radar systems. (Reprints).

UNCLASSIFIED REPORT

ABSTRACT: (U) A Transfer Matrix (TM) Analysis is formulated to predict the natural modes and frequencies of hoop-maypole type satellite antenna systems. Two directions of bending, axial extension/compression and torsion are represented as coupled by feed assemblies canted with respect to the mast, solar panels tilted out of the plane of the center structure and masses offset from the mast centerline. Shear deflections, large steady cable loads and large compressive loads are accounted for in appropriate members. Using properties chosen as representative of such structures, trends are predicted with variations in size and configuration for several simplified configurations; these include, (a) two-dimensional cable-suspended rigid bars on a flexible center body (mast), (b) T and H-shaped center body sub structures in two and three-dimensional vibrations and (c) cable-stiffened, planar polygonal hoop assemblies. IN the last of these cyclic symmetry had to be invoked to avoid numerical difficulties. Some general conclusions are drawn regarding the free vibrations of such structures. The TM approach is seen as a viable alternative to FEM analyses, when structures are encountered which have major substructures with one dimension longer than its others. Full use of the TM analysis for hoop-maypole type structures must await a reformulation in which cyclic symmetry can be invoked, as in the plane hoop cases.

ABSTRACT: (U) From time of the inception of this work,
it became clear at a relatively early stage that the USC
MBE facility required major effort and investment to be
able to grow reliable samples. In an effort to achieve
this aim, the principal investigator was forced to take
responsibility of the MBE growth as well - a situation
not originally anticipated. Accordingly, major effort was
spent making the USC MBE machine operational and putting
in place basic support facilities (such as substrate
cleaning and preparation). The situation with regard to
the MBE machine thus, unfortunately, deprived us of
appropriate GaAs/Al Ga1-xAs samples to be able to proceed
with certain experiments. We did, however, grow a few
GaAs/Alx Ga1-xAs/GaAs tunnelling structures had them
fabricated into actual tunnel structures, and carried ou
Fowler-Norheim resonance tunnelling experiments at JPL.
The results indicated that the interfacial quality of
these structures were rather poor.

ABSTRACT: (U) The purpose of this paper is to discuss some characteristics of the typical cluster size for the self-matching 2-dimensional percolation models. For simplicity the author only describes his results for the site percolation model on double Z squared and leaves the task of extending this discussion to general models to the readers. Let us now introduce the 2-dim site percolation model. Let p denote the probability measure under which all sites of the lattice double Z squared are independently occupied (non-occupied) with probability p (respectively $1-p$). It is said that x is connected to y if there is a nearest neighbor path over occupied sites connecting x and y . (Let w sub $0 = x$ is an element of double Z squared as 0 approaches x) the cluster of occupied sites connected to 0 . This paper is devoted to the study of certain special properties of the typical cluster size about the critical point (p sub $c = \inf(p : p$ sub $p(0$ approaches infinity) > 0)).

UNCLASSIFIED REPORT

SUPPLEMENTARY NOTE: Pub. in IEEE Transactions on Information Theory, VIT-32 n4 p496-512 Jul 86.

ABSTRACT: (U) While delta modulation (DM) simply compares the current predictive estimate of the input with the current sample, delayed delta modulation (DDM) also compares with the upcoming sample so as to detect and anticipate slope overloading. Since this future sample must be available before the present output is determined and the estimate updated, delay is introduced at the encoding. The performance of DDM with perfect integration and step-function reconstruction is analyzed for each of three random input signals. The stochastic stability of the system is established. For a discrete time, independent and identically distributed input, the (limiting) joint distribution of input and output is derived, and the (asymptotic) mean-square sample point error $mse(SPE)$ is computed when the input is Gaussian. For a Wiener input, the joint distribution of the sample point and prediction errors is derived, and $mse(SP)$ and the time-averaged $mse(mse(TA))$ are computed. For a stationary first-order Gauss-Markov input, the joint distribution of input and output is derived and $mse(SP)$ and $mse(TA)$ computed. Graphs of the mse 's illustrate the improvement attainable by using DDM instead of DM. With optimal setting of parameters, $mse(SP)(mse(TA))$ is

ABSTRACT: (U) We have developed a system called LANDSCAN, which is an integrated vision system and the recognition process is knowledge driven. This knowledge is generated by a query in English. The visual information is a stereo pair of images, and the description are being made on 3-dimensional information. Keywords: Computer applications, Image processing, Optical images, Natural language, Computer vision, Knowledge driven recognition, Scene analysis.

ABSTRACT: (U) The problem of calculating the two-terminal reliability of a network having edges that fail randomly and independently is known to be NP-hard, even in the case of directed acyclic networks. This paper discusses an iterative technique that provides at each iteration both upper and lower bounds on the exact reliability value. These bounds are shown to converge to the exact answer for the case of acyclic networks. Computational results indicate that for certain classes of graphs these bounds converge rapidly and provide excellent approximations to the true network reliability. (Author)

ABSTRACT: (U) Let $(\text{sub } 1), \dots, (\text{sub } n), \dots$ be i.i.d.
observations of a random vector (X, Y) where Y is one-
dimensional and X may be multi-dimensional. Suppose that
the regression of Y to X , in some sense, is a linear
function $\alpha \text{ sub } 0 + \beta \text{ sub } 0$. It is desired to
estimate the unknown parameters $\alpha \text{ sub } 0, \beta \text{ sub } 0$,
using the observations $(\text{sub } 1), \dots, (\text{sub } n)$. A much
discussed class of estimates is the so-called M-estimate,
which takes the solution of a certain minimization
problem as the estimator. Here ρ is a properly selected
function defined over $R^p = (\text{infinity})$. (Keywords: linear
models).

UNCLASSIFIED REPORT

ABSTRACT: (U) This grant consisted of two parts: the installation of a Local Area Network and the installation of a network of four graphics workstations. The Local Area Network (LAN) was operational in June of 1986. The department has about 25 terminals connected to the network. Most of the terminals are located in the offices of the faculty and graduate students, with a few in a joint-use equipment room. The response is that this has greatly improved the departmental computing environment. In addition, 7 faculty members have been given microcomputers by the university of New Mexico and these have been connected to the LAN. This configuration seems to provide an excellent computing environment. Some of the faculty have found that current microcomputers are too small and have too little software, so the University will hopefully replace some of these with more powerful micros, which will also be connected to the LAN. This network has and will continue to have a substantial impact on the research and teaching in the department. However, there is no easy way to verify this except through the informal reports of the people using the system. The network of workstations was operational in August of 1985. The network of workstation consists of four Sun-2/160 minicomputers; each has a tape and disk drive. These are connected via an ethernet, which is

AD-A185 486

connected to the university CDCN. The Sun workstations have been upgraded to Sun-3 class workstations; three of the workstations have 4-megabyte memories while one has a 8-megabyte memory; one has floating point accelerator.

UNCLASSIFIED REPORT

ABSTRACT: (U) Compositionally diphasic xerogels. These materials are very intimate mixtures composed of two solid phases each on the order of 10-20 nm. The two phases are only different in composition. Using the multilite (3A1203SiO2) system as the prototype model, we have shown that the compositionally diphasic materials sinter to a much lower temperature than the single phase gels. Such sintering of compositionally diphasic gels at much lower temperatures may be attributed, at least in part, to the heat of reaction of the two discrete phases at the sintering temperature. This notion was extended to other systems such as Al2TiO5, ZrSiO4, ThSiO4 and Mg2Al4SiO18. Results to data on the Al2TiO5, ZrSiO4 and ThSiO4 systems do not show significant improvements in densification behavior although the use of diphasic gels led to a lowering in the crystallization temperatures of ZrSiO4, ThSiO4, etc. The diphasic Mg2Al4SiO18 system exhibits metastable melting which could be used for enhanced densification of this low-expansion ceramic. Using the diphasic approach, we have also prepared translucent ultra-low expansion titania-silica glasses with 0 to 10% TiO2. The coefficients of thermal expansion are intermediate between those of fused silica and a commercial titania-silica glass. The glass with 7.2% TiO2 exhibited a zero thermal expansion coefficient at 150-210

UNCLASSIFIED REPORT

ABSTRACT: (U) This paper defines Y sub 0 to be a geometric convolution of X if Y sub 0 is the sum of N sub 0 i.i.d. random variables distributed as X , where N sub 0 is geometrically distributed and independent of X . It is known that if X is non-negative with finite second moment then as p approaches limit of 0, Y sub 0/EY sub 0 converges in distribution to an exponential distribution with mean 1. Derive is an upper bound for $d(Y$ sub 0), the distance between Y sub 0 and an exponential with mean Y sub 0, namely for $0 < p < \text{or} = 1/2$, $d(\text{sub } 0) < \text{or} = cp$ where $c = \text{sq ex/sq (ex)}$. This bound is asymptotically (p approaches limit of 0) tight.

UNCLASSIFIED REPORT

ABSTRACT: (U) A unified theory of secondary instability in wall-bound shear flows has been developed. This theory rests on Floquet systems of stability equations and permits classification and quantitative analysis of different modes of secondary instability in the three-dimensional stage of laminar-turbulent transition. The catalogue of solutions is consistent with observations and predicts other phenomena that have not been identified in experiments. The theoretical results have been used to reproduce patterns in flow visualizations by computer animation. Analysis of the energy balance has shown a feedback loop between mean flow, two-dimensional, and three-dimensional disturbances that is considered key to the process of self-sustained transition. Various techniques have been developed to investigate details of the nonlinear three-dimensional processes involved in this feedback loop. Keywords: Boundary layer, Stability, Transition.

UNCLASSIFIED REPORT

ABSTRACT: (U) A block-structured solution scheme was developed for the solution of three-dimensional Euler equations around complex geometric configurations. The overall effort included the development of a block-structured solution of both potential and Euler equations. The flow field around a complex geometry is divided into blocks with simple geometries. The computational grid is generated individually for each of the blocks and coupled automatically. For each of the blocks, either potential or Euler equations are solved independently using the finite element method. The normal mass and entropy fluxes are balanced between the blocks iteratively by using a relaxation scheme. This scheme is implemented on large computers (Cray and IBM) using parallel preprocessing capabilities such as asynchronous I/O and several CPU's. Keywords: Transonic flow; Three dimensional; Airfoils; F-16 Aircraft. (Author)

UNCLASSIFIED REPORT

ABSTRACT: (U) In this Phase I study funded under the Small Business Innovation Research (SBIR) program, statistical methods are developed using the predictive inference and entropy approach. Previous recent research has derived entropy as the natural measure of model approximation error from the fundamental statistical principles of sufficiency and repeated sampling. In this study, the areas of nonnested multiple comparison, multivariable time series analysis, adaptive time series analysis of changing processes, and optimal small sample inference are investigated. Constrained maximum likelihood methods are developed for general nonnested multiple comparison. For the asymptotic optimality of these methods, a condition on the Fisher information and Hessian matrices must be satisfied. Applying these results to multivariate time series analysis, lower bounds are derived for the achievable accuracy of the estimated transfer function and spectral matrices. Markov and canonical variate analysis (CVA) provide a means of numerically and statistically stable model fitting of multivariable time series, and these methods provide a basis for modeling fitting time varying models of changing processes.

UNCLASSIFIED REPORT

ABSTRACT: (U) The purpose of obtaining the gene of Adenosinediphosphoribosyl Transferase (ADPRT) is: 1) the complete amino acid sequence of this large protein is best determined from the DNA sequence of the gene, 2) isolation of the gene provides gene probes that permit location and quantitation of the gene within genomic DNA, and 3) a variety of biological experiments at the cellular level requires specific gene probes. The DNA-associating enzyme, adenosinediphosphoribosyl transferase, has been isolated from calf thymus by selective precipitation with a solution of dihydroxy-Reactine Red 120, followed by extraction of the enzyme from the precipitate with 2 M KCl and an on-line train of three successive column chromatographic steps, including a final 3-aminobenzamide-Sepharose-4B affinity chromatography. The method yields 8-9 mg of more than 95% homogeneous enzyme protein per kg starting material and requires about 3 working days. This dye precipitation method is distinct from affinity precipitation, since it involves the binding of the dye to both nonspecific sites and the substrate- and DNA-site of the transferase as indicated by enzyme inhibition by dihydroxy Reactive red 120 at both enzyme sites.

UNCLASSIFIED REPORT

ABSTRACT: (U) This project yielded the following significant new discoveries and findings about solar magnetic fields: The majority of magnetic flux on the sun is observed to disappear when magnetic fields of one polarity migrate into or develop in juxtaposition with fields of opposite polarity. The cancellation of magnetic fields can be interpreted as: (a) submergence (b) reconnection or (c) dissipation (annihilation) of magnetic fields. Large-scale filaments are observed to form in the chromosphere immediately above the boundaries between areas of network magnetic field of opposite polarity where network cancellation occurs. Small-scale filaments develop in association with small-scale cancelling magnetic fields at the rate of hundreds per day. Magnetic fields associated with large-scale solar convection cells, known as intranetwork magnetic fields, can be detected everywhere on the visible disk of the sun by using the videomagnetograph to integrate successive, 1/15 sec. magnetic field images for intervals of 1 to 10 minutes. The intranetwork field appear to be a few seconds of arc in diameter, and have field strengths of the order of a few Gauss to tens of Gauss. The intranetwork fields appear to originate at the centers of supergranules and flow to the boundaries of the cells in approximately radial patterns.

UNCLASSIFIED REPORT

ABSTRACT: (U) The structure of an incompressible turbulent boundary layer subjected to a strong adverse pressure gradient is studied by means of an asymptotic analysis of the Reynolds time-averaged equations. Limit-process expansions developed in the limit of large Reynolds number reveal a relatively thick nondefect layer in the outer region of the boundary layer near the exterior inviscid flow, and a relatively thin layer near the wall. To leading orders of approximation, the momentum balance involves convection, pressure gradient, and turbulent stress in the outer layer, and pressure gradient, and turbulent and viscous stresses in the inner layer. The asymptotic expansions for these two layers are matched in an arbitrary intermediate region, wherein the streamwise velocity has a square-root dependence and the Reynolds stress has a corresponding linear dependence on the normal coordinate. The leading-order approximations for the outer and inner layers give rise to similarity formulations, from which appropriate similarity formulations for the distinguished intermediate layer have been identified and developed. These latter formulations are employed to analyze available experimental data.

ABSTRACT: (U) This document considers a class of steady-state semi-linear reaction-diffusion problems with non-differentiable kinetics. The analytical properties of these problems have received considerable attention in the literature. The first step in analyzing their numerical approximation is taken. The authors present a finite element method and establish error bounds which are optimal for some of the problems. In addition, a finite difference approach is also discussed. Numerical experiments for one and two-dimensional problems are reported. (Author)

ABSTRACT: (U) Results on the numerical and analytic solution of implicit systems of differential equations and their application to circuit and control problems were developed. In particular, the first general algorithm for the linear time varying case was developed along with an analysis of how to apply it to certain control problems. New structure theorems provide insight on the convergence of backward differentiation formulas and guidelines for their use. (Author)

ABSTRACT: (U) This report summarizes two phases of the research project. The first phase dealt with the strength and behavior of steel fiber reinforced concrete subjected to biaxial compression-tension loadings. A new piece of direct tension loading apparatus was designed and assembled for this study. Load history effects on the degradation of the tensile strength were also investigated. The second dealt with the modeling of a buried culvert system, both numerically and in the geotechnical centrifuge. The centrifuge test results were compared to the numerical analytical results to provide a validation of the numerical algorithm in which constitutive models could be incorporated.

ABSTRACT: (U) Of the molecules measured with EFISH there is a striking constancy of their microbeta products and even the more approximate beta's themselves. These molecules are all nitrobenzene derivatives and the observation could be made that the magnitude of beta is more or less tied to this conjugated portion of the molecules. Comparison of the power data with the molecular hyperpolarizabilities illustrates that a study of powder response tells essentially nothing whatever about molecular properties. Attention should be directed to crystal studies in the search for materials destined for application to the processing of weak optical signals. The dependence of molecular polarizability on concentration in some solvents for some solutes at very low concentrations has not been clearly seen before. These measurements were all made on solutions of less than 1 molecular percent and so solute-solute interaction almost certainly is absent.

ABSTRACT: (U) One paper produced in this effort dealt with the importance of intermediate boundary conditions for approximate factorization schemes. A second paper derived stability results for spectral methods applied to initial-boundary value problems for hyperbolic systems. The paper demonstrates that one can bound certain weighted L2 spatial norms of the solution in terms of norms of the boundary data. A third paper deals with domain decomposition methods in the content of spectral techniques. Stability and convergence results are obtained for one and two dimensional cases.

ABSTRACT: (U) A brief description of equipment acquired under the present grant is provided, along with a list of equipment. The equipment has enhanced molecular beam epitaxial growth and characterization capabilities in the principal investigator's laboratory.

DESCRIPTORS: (U) *AEROSPACE CRAFT, *AERODYNAMIC FORCES, NAVIER STOKES EQUATIONS, BOUNDARY VALUE PROBLEMS, WEIGHTING FUNCTIONS, CONVERGENCE, STABILITY, POTENTIAL FLOW, TRANSONIC CHARACTERISTICS, LEGENDRE FUNCTIONS, CHEBYSHEV APPROXIMATIONS.

ABSTRACT: (U) This document describes the structure of most of these processes and discuss some of their basic properties. The coverage does not include several important topics requiring lengthy mathematical development (e.g. martingale theory of point processes, general Palm probabilities, and ergodic and spectral analysis of stationary processes). The emphasis will be one presenting tools for modeling stochastic systems rather than on applications of the tools. Although the theory of point processes is intimately connected with the subject of measure and integration (a point process is a random counting measure). The author focused on results that can be understood without a deep knowledge of measure theory. On the other hand, the presentation will be rigorous and at the level of the applied probability literature that one would encounter in studying point processes. (Author)

UNCLASSIFIED REPORT

ABSTRACT: (U) Ambient and elevated temperature tensile and creep response, and microstructural stability of a powder processed Al-Fe-Ce alloy have been evaluated. Gas atomized Al-Fe-C was mechanically alloyed (MA) to give a volume fraction of dispersoids of about 0.23. The powder was could isostatically pressed in aluminum cans, outgassed and hot extruded to full density. Consistent with improved microstructural stability at elevated temperatures, the MA material is stronger and more creep resistant than the non-MA material. These improvements are attributed to the presence of fine scale oxides and carbides distributed uniformly throughout the structure, and which are introduced during MA; the dispersion inhibits coarsening, recovery and recrystallization. Non-MA Al-Fe-Ce is stronger than non-MA Al-Fe-Ni at all temperatures but it has limited ductility. Qualitatively, the effect of MA on Al-Fe-Ce is similar to that in Al-Fe-Ni. These results suggest that Ce alters the transformation characteristics of Al-Fe and/or that Ce diffuses more slowly than Ni in Al, in the presence of Fe.

UNCLASSIFIED REPORT

ABSTRACT: (U) Unified explicit analytical solutions for the (non-axisymmetric) first and second boundary value problems of elasticity theory for a spheroidal cavity embedded in a transversely isotropic medium are presented. The analysis is based upon solutions of the homogeneous displacement equations of equilibrium in terms of three quasi-harmonic potential functions, each of which is harmonic in a space different from the physical space. Thus, three spheroidal coordinate systems with different metric scales (one for each potential) are introduced such that the three coordinate systems coincide on the spheroidal cavity. These potential functions are taken in a unique combination of the associated Legendre functions of the first and second kind. Extensive numerical data are obtained for the stress concentration factors associated with axisymmetric and non-axisymmetric problems for a variety of materials. The effect of anisotropy on the stress concentration factor is discussed in much greater detail than has been previously available in the literature.

UNCLASSIFIED REPORT

ABSTRACT: (U) Transfer matrices and joint coupling matrices are used to compute natural frequencies of vibration of a five-bay planar lattice structure. The method of analysis may be applied to general two and three-dimensional lattices. The necessary numerical computations may be performed easily with a personal computer. Numerical results for the first twenty-five nonzero natural frequencies of the five-bay planar lattice structure are given for the case when the members of the lattice are modeled as Bernoulli-Euler beams, and for the case when the members of the lattice are modeled as Timoshenko beams. The maximum difference in the computed natural frequencies of the two models occurs in the twenty-fifth mode and is less than one-half of one percent. The natural frequencies obtained here agree within six percent with the natural frequencies obtained in a previous analysis using a finite element method and an experimental modal analysis.

UNCLASSIFIED REPORT

ABSTRACT: (U) The model ionosphere was developed that is coupled to a magnetospheric model for investigating time dependent behavior of the Polar F-region ionosphere in response to varying interplanetary magnetic field (IMF) configurations. The numerical ionospheric model covers a latitude range from 50 to 90 degrees and an altitude range of 150 to 600 KM. The purpose of the magnetospheric model is to define the location and geometry of the polar cap, which is defined as the region of open field lines. The polar cap configuration has been coupled to a model electric field pattern that in turn may vary in size and strength in response to the IMF. The ionosphere model assumes only oxygen ions; the ion density is solved vertically along many magnetic field lines as they move horizontally under the influence of the large-scale convective electric fields. The lower boundary is defined by the local chemistry and the upper boundary condition has been set by applying an outward flux of ions appropriate for open field line conditions. The model has been used to illustrate ionospheric behavior during geomagnetic storms conditions. Future model applications may include ionospheric prediction using IMF inputs improved understanding of polar ionization structures.

ABSTRACT: (U) The first phase of this program was investigation of triquinoyl hydrate (hexaketocyclohexane octahydrate, C₆H₁₈O₁₄) which is formed when certain cyclohexane derivatives are treated with cold nitric acid. This ketone hydrate has now been characterized by measurements of its elemental composition, x-ray diffraction pattern, density, infrared and Raman spectrum, carbon thirteen NMR pattern, ultraviolet absorption and fluorescence spectra, ion chromatogram, potentiometric titration curve, solubility, rate of weight loss at several temperatures, heat of decomposition and of combustion, and reactivity toward several different nucleophiles, reducing agents and oxidizing agents. The ketone hydrate is an unusually dense, tightly hydrogen-bonded, acidic, crystalline material which in solution rapidly undergoes dehydration, disproportionation and ring-opening reactions. It may be regarded as a graphite oxide (graphitic acid) having the maximum oxygen-to-carbon ratio.

ABSTRACT: (U) Second order turbulence closure models for conditional moments and the intermittency factor were developed. Methods for the treatment of turbulent/non-turbulent and other scalar interfaces were applied to the plane mixing layer and round jet. Multiscale closure models based on the dissipation rate were developed and applied to homogeneous turbulence and the plane jet. Scalar transport was investigated using the separation probability of clusters of particles and numerical solutions based on stochastic simulation techniques. A direct extension of conditional closure to velocity-scalar pdf equations was also developed.

ABSTRACT: (U) Summary of major research findings in three topical areas: 1) traveling wave concepts in the dynamics and control of large space structures, 2) passive damping in large space structures applications, and 3) active control of rigid and flexible manipulator arms. The traveling wave concepts for characterizing the dynamics of flexible structures have introduced an alternative to modal synthesis and established a basis for the development of new controls algorithms. Passive damping studies identified various types of damping mechanisms including thermoelastic, and electromagnetic, and quantified their relative contributions. The active control studies generated a number of algorithms and control strategies and demonstration applications.

ABSTRACT: (U) Analogues of Freidlin and Wentzell's estimates for diffusion processes and the functional law of the iterated logarithm are obtained for a class of stochastic processes represented by multiple Wiener integrals with respect to two parameter Wiener processes, which arise as the limit processes of sequences of normalized symmetric statistics. (Author)

ABSTRACT: (U) The objective of the project was to graphically represent data obtained in the course of solving equations of fluid dynamics. Studies of three-dimensional data were done with data arising from a fluid dynamics problem involving high temperatures and velocities. Three representational methods were used: (1) particle tracings showing vectors pointing in the direction of flow at a point, (2) representation of contours, and (3) ray tracing, with color values assigned to a cell depending on the values of some quantity such as density.

ABSTRACT: (U) This paper is devoted to an analytical
comparison of the various elliptic partial-differential-
equation (PDE) models which are in current use for grid
generation. These comparisons, particularly between the
equations from the Laplace-Poisson system and the
equations from a Gaussian approach, have yielded useful
expressions connecting the 3D Laplacians and the surface
Beltrami. This effort has specifically been successful
when the transverse coordinate leaving the surface is
orthogonal to the surface. Equations which are derivable
from Cartesian-type Poisson equations and those obtained
by using the variational principle in surface coordinates
have also been considered. (Author)

ABSTRACT: (U) This document considers a parameterized
family of two-stage stochastic control problems with
nonclassical information patterns, which includes the
well-known 1968 counterexample of Witsenhausen. It is
shown that whenever the performance index does not
contain a product term between the decision variables,
the optimal solution is linear in the observation
variables. The parameter space can be partitioned into
two regions in one of which the optimal solution is
linear, whereas in the other it is inherently nonlinear.
Extensive computations using two-point piecewise constant
policies and linear plus piecewise constant policies
provide numerical evidence that nonlinear policies may
indeed outperform linear policies when the product term
is present. (Author)

ABSTRACT: (U) Trans-Chlorotetrafluoro(trifluoromethyl) sulfur(VI), CF₃SF₄Cl, readily undergoes reductive defluorination to sulfur (IV)-containing compounds when it is reacted with nitrogen- or oxygen-containing nucleophiles. Thus, CF₃S(NR₂)₂Cl results from a variety of nitrogen bases, such as R₂NH = piperidine, 2,6-dimethylpiperidine, 2,2,6,6-tetra-methylpiperidine, morpholine, 3,5-dimethylmorpholine, and N,N'-dimethylethylenediamine. With alcohols, CF₃S(ORf)₂Cl is formed where RFOH = 2,2,2-trifluoroethanol and 1,1,1-trifluoro-2-propanol. Due to the low stability of all of these compounds, complete characterization was difficult.

ABSTRACT: (U) Positively invariant regions for the system $\dot{t} + p(w)$ sub $x = \epsilon$ sub w sub $t - v$ sub $x = \epsilon w$ sub xx are constructed where $p' < 0$, $w < \alpha$, $w > \beta$, $p'(w) = 0$, $\alpha < w < \beta$, $e > 0$. Such a choice of p is motivated by the Maxwell construction for a van der Waals fluid. The method of an analysis is a modification of earlier ideas. The results given here provide ϵ independent L at infinity bounds on the solution (w, v) .

ABSTRACT: (U) New results are given on the pole-shifting problem for commutative rings, and these are then applied to conclude that rings of continuous, smooth, or real-analytic functions on a manifold X are PA rings if and only if X is one-dimensional. This paper establishes new results regarding control problems for parametrized families of pairs ('systems').

ABSTRACT: (U) A controller is shown to exist, universal
for the family of all systems of fixed dimension n with m
controls, which stabilizes those systems that are
stabilizable whenever certain gains are large enough. The
controller parameters are polynomial functions of the
entries of the plant. As a consequence, a result is
proved on polynomial stabilization of families of systems.

ABSTRACT: (U) The classical algorithms of Schur and Levinson are efficient procedures to obtain the triangular factorization of, respectively, a Hermitian Toeplitz matrix and its inverse. Extensions of the Schur algorithms to Hermitian Quasi-Toeplitz (Q-T) matrices (matrices with certain hidden Toeplitz structure) and the Levinson algorithm to admissible (a sub-class of) Q-T matrices are also known. This paper extends these Schur and Levinson algorithms to non-Hermitian Q-T matrices. The fast algorithms for non-Hermitian Q-T matrices are shown to be associated with two discrete transmission lines which reduce to the familiar single lattice in the Hermitian case.

ABSTRACT: (U) The important problem of Adaptive Line Enhancing (ALE) is addressed in this paper. Its solution involves an Adaptive Notch Filter (ANF) proposed in references using a minimal parameter constrained infinite impulse response (IIR) model in conjunction with the Recursive Prediction Error Method (RPEM). A Fast Transversal Filter (FTF) algorithm for the adaptive RLS-type updating of the linear phase filter is presented. (Author)

ABSTRACT: (U) The class of new better than used in expectation life distributions is shown to be closed under the formation of parallel systems with independent and identically distributed components. The class of differentiable life distributions with decreasing mean residual life is also proved to have the same closure property.

SUPPLEMENTARY NOTE: Pub. in IEEE Transactions on Automatic Control, vAC-32 n7 p641-645 Jul 87.

ABSTRACT: (U) This project has initiated an ongoing study of singular stochastic control problems of the finite-fuel type, and their relations to questions of optimal stopping. These problems are studied here mainly by analytical techniques; they lead to explicitly solvable free boundary problems, and to simpler questions in stochastic optimization, such as families of optimal stopping problems, and singular control with unlimited fuel.

ABSTRACT: (U) Motivated by the results on steady-state periodic tracking, a continuous-time nonzero set point regulation problem is considered which involves 1) noisy and nonnoisy measurements, 2) weighted and unweighted controls, 3) correlated plant/measurement noise and cross weighting, 4) nonzero-mean disturbances, and 5) state-, control-, and measurement-dependent white noise. It is shown that in the absence of multiplicative disturbances the closed-loop control can be designed independently of the open-loop control. The results are obtained without using the overtaking criterion.

ABSTRACT: (U) The optimal projection equations obtained
for reduced-order, discrete-time state estimation are
generalized to include the effects of state- and
measurement-dependent noise to provide a model of
parameter uncertainty. In contrast to the single matrix
Riccati equation arising in the full-order (Kalman filter)
case, the optimal steady-state reduced-order discrete-
time estimator is characterized by three matrix equations
(one modified Riccati equation and two modified Lyapunov
equations) coupled by both an oblique projection and
stochastic effects.

ABSTRACT: (U) This project is intended to combine:
pattern recognition, image understanding and artificial
intelligence techniques for space-based image processing
as well as: optical and digital processing methods.
Optical feature extraction and sub-pixel target detection
and tracking results are summarized. Scene representation
and modeling work using: probabilistic graph matching,
multiple resolution rotation-invariant operators and
texture analysis are detailed. Image understanding
techniques for 3D scene interpretation discussed include
2D image-level methods (using features such as edges,
lines and corners) and 3D scene-level methods. New
dynamic programming, stereo image and model building
results are included.

ABSTRACT: (U) The author considers an undirected network
G with node set V and arc set $E = (1, \dots, n)$ where arcs
fail randomly and independently. Let T be a subset of V
and let M sub k denote the number of ways that all the
nodes of T are connected (T-connectivity) with exactly k
operating arcs and n - k failed arcs. This paper
describes a sampling plan for estimating (M sub k) and
linear functions of these parameters, including the T-
connectedness reliability function g(p) for common
failure probability 1 - p.

ABSTRACT: (U) Steady-state linear laser induced
fluorescence (LIF) has been used to investigate internal
energy redistribution rates in A2 delta v' = 0 CH in a
low pressure oxy-acetylene flame. By obtaining
rotationally resolved spectra as a function of pressure
the branching ratio, defined as the ratio of rotational
transfer (R) out of the laser excited state divided by
the electronic quenching rate (Q), was measured for a
variety of flame conditions. For a stoichiometric 1800K
flame and $K' = 6$ excitation $R/Q = 3.6 \pm 0.5$. The
branching ratio was also found to increase with K' and
decrease with equivalence ratio. In addition, for $K' = 6$
excitation, a value of the electronic quenching cross
section of $5.4 \pm 0.3 \times 10^{-16}$ cm² was obtained.

ABSTRACT: (U) Spectral necessary and sufficient conditions are derived for stationary symmetric stable processes to be metrically transitive and mixing. Then consider some important classes of stationary stable processes: Sub-Gaussian stationary processes and stationary stable processes with a harmonic spectral representation are never metrically transitive, the latter in sharp contrast with the Gaussian case. Stable processes with a harmonic spectral representation satisfy a strong law of large numbers even though they are not generally stationary. For doubly stationary stable processes, sufficient conditions are derived for metric transitivity and mixing, and necessary and sufficient conditions for a strong law of large numbers.

ABSTRACT: (U) The authors introduce the problem with an example. How should we design an experiment to compare 4 test treatments with a control, using 18 experimental units? As a statistical question we will not be able to answer it unless it is asked in a more precise manner. To begin with we need to postulate a model for the response observed upon application of a treatment, test treatment or control, to an experimental unit. This paper shall consider three possible models: 1) 0-way elimination of heterogeneity model in which all experimental units are homogeneous before application of treatments; 2) 1-way elimination of heterogeneity model in which experimental units can be divided into several homogeneous blocks; and 3) 2-way elimination of heterogeneity model in which the experimental units can be conceptually arranged according to rows and columns.

ABSTRACT: (U) Quadtree representation of matrices offers a homogeneous representation for both sparse and dense matrices, with advantages for processing on multiprocessors. This paper offers exact values for the average depth and on the number of nodes in this representation of some familiar patterned matrices: symmetric, triangular, and banded. It similarly measures three permutation matrices as comparative examples of non-dense, unpatterned matrices. Those results are exact values for the shuffle and bit-reversal permutations raised by the fast Fourier transform, as well as tight bounds on the expected values from purely random permutations. Two different measures for density and for sparsity are proposed from these values, and a simple analysis of quadtree matrix addition is given as an illustration of these measures. (Author)

ABSTRACT: (U) This paper demonstrates the equivalence of the Euler and the Lagrangian equations of gas dynamics in one space dimension for weak solutions which are bounded and measurable in Eulerian coordinates. The precise hypotheses include all known global solutions on $R \times R^+$. In particular, solutions containing vacuum states (zero mass density) are included. Furthermore, there is a one-to-one corresponding admissibility criteria are equivalent. In the presence of a vacuum, the definition of weak solution for the Lagrangian equations must be strengthened to admit test functions which are discontinuous at the vacuum. As an application, we translate a large-date existence result of DiPerna for the Euler equations for isentropic gas dynamics into a similar theorem for the Lagrangian equations.

SUPPLEMENTARY NOTE: See also Volume 5, AD-A185 133.

ABSTRACT: (U) Contents: Secondary instability of free shear flows, positive and negative effective viscosity phenomena in isotropic and anisotropic Beltrami flows.

ABSTRACT: (U) Contents: Weak interactions and local order in strong turbulence; relation between the Kolmogorov and Batchelor constants; an efficient method or computing leading eigenvalues and eigenvectors of large asymmetric matrices.

DESCRIPTORS: (U) *TURBULENCE, *DIGITAL SIMULATION, SHEAR STRESSES, VORTICES, NAVIER STOKES EQUATIONS, TWO DIMENSIONAL FLOW, REYNOLDS NUMBER.

DESCRIPTORS: (U) *TURBULENCE, *DIGITAL SIMULATION, CHANNEL FLOW, DECAY SCHEMES, LINEAR ALGEBRA, MATRICES(MATHEMATICS), EIGENVECTORS, EIGENVALUES, COMPUTATIONS, ASYMMETRY, GROUPS(MATHEMATICS), EDDIES(FLUID MECHANICS).

IDENTIFIERS: (U) Mixing layers, Beltrami flow.
WUAFOSR2307A2, PEG1102F.

IDENTIFIERS: (U) Kolmogorov constant, Batchelor constant, Weak interactions, Renormalization. WUAFOSR2307A2, PEG1102F.

ABSTRACT: (U) For sequential decision processes, we
consider the problem of obtaining the min-max strategy
which minimizes the worst case performance. This is a
game against nature, attempts to maximize it. It is
apparently a folk theorem that such a min-max strategy
can be obtained by means of a dynamic programming like
recursion, even though we have not seen any general proof
of this, applicable to stochastic systems, which does not
rely on the existence of a saddle point. We prove this
theorem and also examine the precise roles of the
strategy sets allowed to the minimizer and the maximizer
in determining the upper value of the game. Improvements
in the results for the case of deterministic systems and
generalizations to continuous time systems are indicated.

DESCRIPTORS: -(U) *MINIMAX TECHNIQUE, DYNAMIC PROGRAMMING,
OPTIMIZATION, STOCHASTIC PROCESSES, CONTROL SYSTEMS,
REPRINTS.

IDENTIFIERS: (U) Markov chains.

UNCLASSIFIED REPORT

ABSTRACT: (U) Hierarchical models are important in Bayesian prediction because they enable the use of collateral data from related risks with exchangeable parameters. The classical normal-normal model with random means show clearly how the linear predictive mean for a single risk is improved by the availability of cohort data. However, this model has the disadvantage that the predictive density is homoscedastic, that is, the posterior, variance depends only on the design (number of risks and number of samples). In most applications, one would assume that the variance also depended upon the data values. One can, of course, change the variances at each level into random parameters, but this modifies the predictive mean formulae and leads to messy results in general. In the course of examining approximations to predictive variances, the author has found an extended normal model with variances that are quadratic in the data, and with the additional advantage that the linear mean formulae are unchanged.
